

Building Life-Cycle Analysis with the GREET

Building Module: A User Guide

Energy Systems and Infrastructure Analysis Division

About Argonne National Laboratory

Argonne is a U.S. Department of Energy laboratory managed by UChicago Argonne, LLC under contract DE-AC02-06CH11357. The Laboratory's main facility is outside Chicago, at 9700 South Cass Avenue, Argonne, Illinois 60439. For information about Argonne and its pioneering science and technology programs, see www.anl.gov.

DOCUMENT AVAILABILITY

Online Access: U.S. Department of Energy (DOE) reports produced after 1991 and a growing number of pre-1991 documents are available free at OSTI.GOV (<http://www.osti.gov/>), a service of the US Dept. of Energy's Office of Scientific and Technical Information.

Reports not in digital format may be purchased by the public from the National Technical Information Service (NTIS):

U.S. Department of Commerce
National Technical Information Service
5301 Shawnee Rd
Alexandria, VA 22312
www.ntis.gov
Phone: (800) 553-NTIS (6847) or (703) 605-6000
Fax: (703) 605-6900
Email: **orders@ntis.gov**

Reports not in digital format are available to DOE and DOE contractors from the Office of Scientific and Technical Information (OSTI):

TABLE C2. Aggregated Life cycle profile of Aniline. Data is stored at the life cycle stage for stages A1, A2, A3, B, C1, C2, C3, C4, and D. Data is also aggregated to the system boundary (Cradle to Gate – Cradle to Cradle).	84

ACKNOWLEDGMENTS

This work was supported by the Building Technologies Office (BTO) of the Office of Energy Efficiency and Renewable Energy of the US Department of Energy (DOE) under contract DE-AC02-06CH11357. We thank Dale Hoffmeyer, Adam Hasz, Joan Glickman, and Sven Mumme of BTO for their support and guidance on this work. We thank Joshua Kniefel of National Institute of Standards and Technology for his feedback and suggestions on the Module development. We thank Luke Leung and Arathi Gowda of Skidmore, Owings & Merrill (SOM) for inputs, data sharing, and specific applications of the Module for whole building LCA. The views and opinions expressed in this publication are solely those of the authors and do not state or reflect those of the US government or any agency thereof. Neither the US government nor any agency thereof, nor any of their employees, makes any warranty, expressed or implied, or assumes any legal liability or responsibility for the accuracy, completeness, or usefulness of any information, apparatus, product, or process disclosed, or represents that its use would not infringe privately owned rights.

SUMMARY

This User Guide provides instructions about how to conduct both the building material-level LCA and whole building LCA with the GREET Building Module. We have developed the GREET Building Module on the GREET Excel platform to leverage extensive background data available in GREET1, GREET2, and those newly generated within the Module. All the background data are fully accessible, editable, and expandable to maintain transparency, consistency, and capability to address different building systems that encompass individual building materials, components, technology solutions, as well as whole buildings and building designs.

The GREET Building Module develops an organic connection between the building material-level LCA modeling and whole building LCA modeling. The modeling results of individual building materials are automatically added to the background database of building materials, which provides a growing database of material options for architects, designers, and researchers to explore and address building sustainability during the building design, building material/component selections, and whole building LCA. The sustainability impacts of newly developed material choices that could be considered for whole building designs can be addressed through detailed, process-level LCA with the material-level modeling platform in the GREET Building Module. This closes the loop of building material supply chain for whole building design, construction, and operation. With both the material-level and whole building LCA capabilities, the GREET Building Module aims to provide detailed embodied energy use and emissions so that stakeholders can examine co-benefits and/or trade-offs between embodied operational sustainability impacts of building materials, components, technology solutions, as well as whole buildings and building designs.

With an interactive and step-by-step modeling framework, the GREET Building Module may be used by LCA researchers, building material developers, building owners, as well as architects and building designers and engineers to evaluate and compare building sustainability performance with consideration of embodied energy use and emissions and promote development, design, and application of sustainable building materials and whole building designs and operations. As the building community is moving fast towards decarbonization of the building and construction sectors, the GREET Building Module will continue to evolve and expand to include new building materials and technologies, to address emerging sustainability issues facing the building and construction sectors, and to help provide reliable insights to improve their sustainability.

Besides this User Guide, the GREET website (<https://greet.es.anl.gov>) presents all publications on development and research with the GREET suite models, including technical reports, technical memos, journal articles (those with open access from individual journals), and journal article abstracts (those without open access from individual journals). These are technical documentation of GREET LCA development and applications, from which the GREET Building Module benefits.

As in the past, users can send inquiries, questions, and comments to greet@anl.gov via email. For speedy responses from Argonne to the questions and comments directed to the GREET Building Module, please include GREET Building Module & LCA in your email subject line if your questions and comments are about the GREET Building LCA Module.

INTRODUCTION

As the buildings sector moves to holistically address environmental sustainability such as greenhouse (GHG) emission reductions, the embodied energy and environmental footprints of buildings and building components, as well as buildings operations, need to be quantified for improvements. Analyzing energy and emissions throughout the life cycle of buildings help our understanding of the sustainability of different building materials along with building design choices and decisions. With the support of the Building Technologies Office of the U.S. Department of Energy's Energy Efficiency and Renewable Energy Office, we have developed a building life-cycle analysis (LCA) module that integrates with the Greenhouse gases, Regulated Emissions, and Energy use in Technologies (GREET[®]) model to leverage extensive background data available from the long history of GREET development. We call it GREET Building Module.

The GREET Building Module is designed to be a transparent, consistent LCA tool for bottom-up assessment of embodied GHG emissions, energy use, and criteria air pollutant emissions across the supply chain of building materials, building technologies, and whole buildings. With an interactive step-by-step graphical user interface, the GREET Building Module enables users to conduct detailed, bottom-up LCA of specific building materials, components, and whole buildings. The GREET module includes conventional and new building materials and helps inform research and development (R&D) efforts of new building materials and components, as well as whole building designs and material choices for achieving reduced embodied energy use and emissions of building components and whole buildings. We hope that the GREET Building Module can inform technology developers, researchers, manufacturers, building designers and architects, and policy makers to holistically address embodied GHG and sustainability performance of building materials and whole buildings with a publicly accessible LCA tool with consistent and extensive background data.

The GREET Building Module is developed on a Microsoft Excel platform. It is synchronized with the Excel versions of GREET Fuel Cycle and Vehicle Cycle models (i.e., GREET1_2022 and GREET2_2022) to share data such as process energy types and common materials between each other. The GREET Building Module is included in the release package of the Excel versions of the GREET suite models. It is also available for download as a standalone module directly at the GREET website (<https://greet.es.anl.gov>) free of charge after a short user registration. The user can refer to a technical report for details about the methodology, data, and sample modeling results of the module (Cai et al., 2021a).

This User Guide aims to provide details about the structure, features, modeling techniques, and applications of the module for conducting both the building material-level LCA and whole building LCA. It adds the following new modeling features and capabilities to the 2021 version of the module (Cai et al., 2021b).

The Building Component Analysis module has been augmented to support time series modeling. Materials can be modeled in any year past 2020, and each subcomponent of a material can use a different year of data as surrogate. This means a material can be modeled in 2030,

while using data for materials from 2020 as surrogate when the actual data is not available. When a material is modeled, GREET1 and GREET2 time-series data will be pulled to match the year the material is being modeled in.

The Whole Building Analysis Module has been augmented to provide options for sensitivity analysis. A Bill of Materials for a building, whence run through the initial LCA, can be set up for sensitivity analysis. The quantity, material type, loss factor, replacement period, and adjustment factor can be set up for each individual material, and the changes in emissions analyzed for each separate factor.

The Whole Building Analysis module has been augmented to allow for disaggregated life cycle results. Life Cycle Analysis results can be aggregated to the system boundary or disaggregated and calculated at each life cycle stage.

The LCProfiles database has been expanded into two worksheets to handle the disaggregated whole building analysis, as well as the time series analysis functions. The LCProfiles worksheet now stores the life cycle profiles of materials, aggregated to the Cradle to Gate life cycle stage. The new Aggregated LCProfiles worksheet stores the life cycle profiles of materials at each life cycle stage, as well as aggregated to the system boundary of the material. Both worksheets store life cycle data for each material for time series analysis as well. The Building Component Analysis module will always use Cradle to Gate data for materials, and therefore uses the LCProfiles worksheet. The Whole Building Analysis module uses the Aggregated LCProfiles database, as it can use material data beyond the cradle to gate boundary.

The Data Gaps feature of the Building Component Analysis module has been improved to allow the user to view and resolve the data gaps of the material loaded into the module, in addition to being able to view data gaps for all materials. The user can additionally see what years of data are available for a given material in a table on the BCA Dashboard.

Forward and backwards propagating LCA have been added to BC Analysis. Backwards Propagating LCA will recursively run LCA on all subcomponents of a material before running LCA on the material itself. Forward LCA will allow the user to select a group of materials that use the selected building material as a subcomponent, and additionally run LCA on those selected materials, to propagate the change in a material's life cycle profile upwards.

A "Material Updates" list has been added to BC Analysis. This list keeps track of what materials are updated, and marks which materials also need to be updated due to using the original material as a subcomponent. This list is also connected with the forward propagating LCA feature, allowing the user to quickly update any materials that need to be re-run due to subcomponent updates.

OVERVIEW OF THE GREET BUILDING MODULE

When the GREET Building Module is opened up, four worksheets will show up by default: 1) an Overview worksheet to notify the copyright of this tool, as well as a brief introduction to the functionality and purposes of a list of worksheets in the Module; 2) a Building Module that provides an overview of the structure of the Module; 3) a building material-level

modeling platform called building component (BC) Analysis; and 4) a whole building LCA modeling platform called Whole Building Modeling.

To begin either the building material-level or the whole building LCA with the Module, a new user could start with the Building Module worksheet, as shown in Figure 1. From there, the Building Components button will take the user to the BC Analysis worksheet to perform detailed building material-level LCA modeling, and the Whole Buildings button will take the user to the Whole Building Modeling worksheet to conduct whole building LCA modeling. A list of interactive buttons will grant the user access to background data worksheets. These background data worksheets are hidden by default to avoid unintentional changes to the data, but the access to them offers the user transparency of the default databases and details of the modeling results. In addition, a button named “Import data from GREET1/GREET2” functions to fetch the latest background data from GREET1 and GREET2 to update the default databases with annual expansion and updates from the GREET1 and GREET2 models.

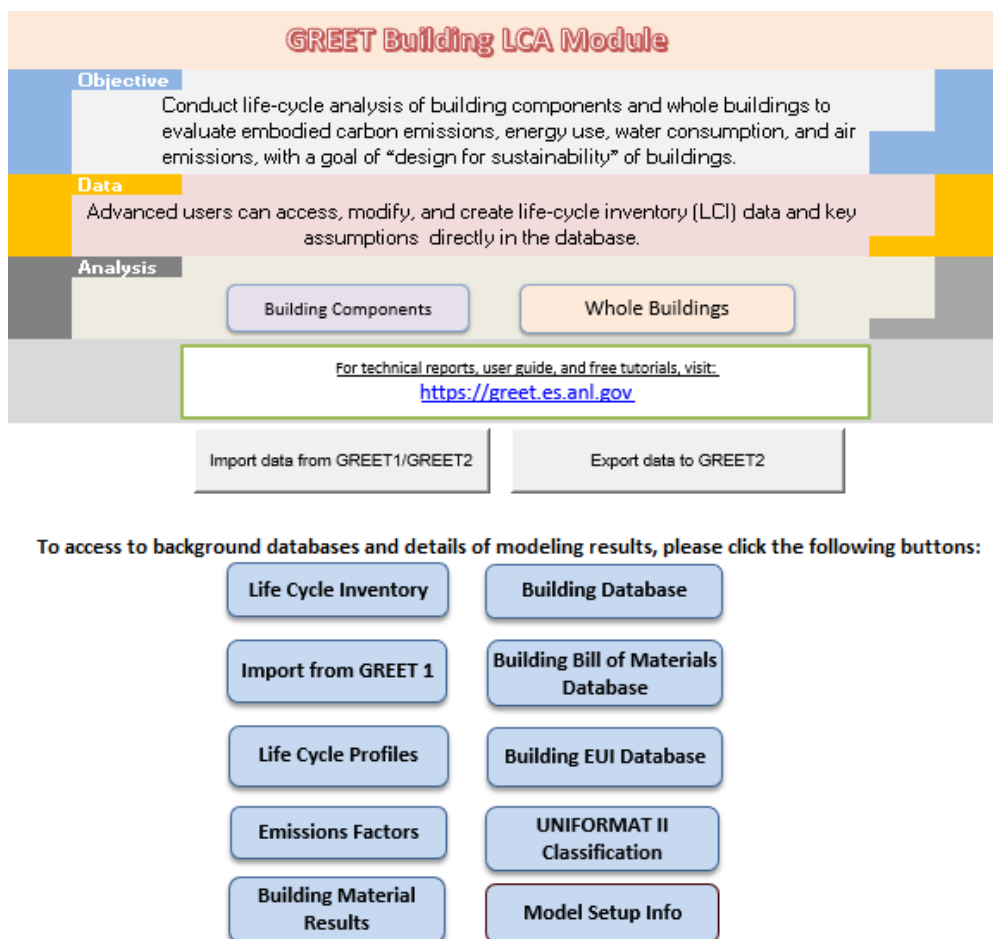

FIGURE 1: Overview of the GREET Building Module

In the following sections, we introduce the Graphical User Interface (GUI), features, and best practices to conduct detailed building material LCA and whole building LCA.

A BUILDING MATERIAL MODELING

A1 OVERVIEW OF THE BUILDING MATERIAL LCA PLATFORM

The building material LCA platform is located in the BC Analysis worksheet, as shown in Figure A1. It is designed to conduct process-level, detailed LCA to address embodied GHG and energy impacts of individual building materials, building components, and building technology solutions for a given system boundary that could vary from Cradle-to-Gate to Cradle-to-Cradle (Cai et al., 2021). A Graphical User Interface (GUI) is designed to provide an interactive modeling experience with quick access buttons to guide the user through the modeling process. The user will be prompted with pop-up data-entry windows to enter detailed life cycle inventory (LCI) data along the life-cycle stages that belong to a selected system boundary. An instructive step is available for the user to identify and address data gaps before running the simulation, and therefore, to improve the accuracy of the modeling. Once the simulation is completed, a dynamic Dashboard is available for the user to view, explore, and interpret the LCA results in detail. The Dashboard also provides an intuitive approach to visualizing detailed LCA results of selected building materials and compare the detailed LCA results of different building materials. When the simulation is completed, the newly generated LCA results will be aggregated to the selected system boundary and added as new data to the LCProfiles worksheet, ready to be used as process material that may be required to manufacture a new building material, building component, or building technology solution, and to be used as a new material option for designers and architects to consider when conducting a whole building/building design LCA with the Whole Building Modeling platform.

A2 CREATE A NEW BUILDING MATERIAL/COMPONENT

To begin a modeling, click on the “Create New Component” button in the top right corner. A pop-up window will show up prompting the user to enter a name for the new building material/component, as shown in Figure A2. Note that material names must not contain brackets or copy the name of an existing material because duplicated names are not allowed in the Module.

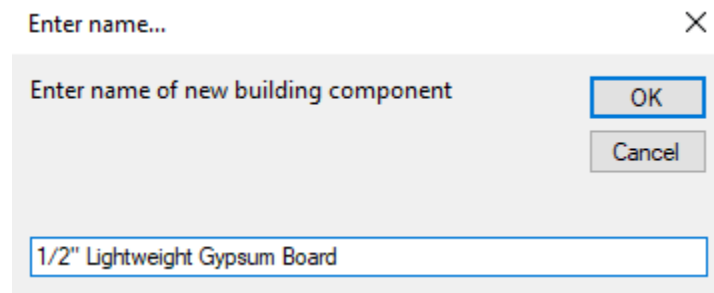

FIGURE A2: The pop-up window for entering the name of a new building

A3 SPECIFY THE LCA SYSTEM BOUNDARY AND FUNCTIONAL UNIT

Once a new building material is named, the next step is to specify the LCA system boundary and functional unit, two major methodology aspects as described in Cai et al. (2021). The user needs to 1) define an appropriate functional unit from a dropdown list, as shown in Figure A3. If a desired functional unit is not available from the default dropdown list, the user can go to the Building Module worksheet, click the “ModelSetupInfo” button to be taken to the “ModelSetupInfo” worksheet to add a new functional unit of interest in the next empty cell of Column A, as shown in Figure A4; 2) select a system boundary from a dropdown list, as shown in Figure A5. The life cycle stages will update accordingly to comply with the selected system boundary, providing an intuitive modeling experience for the user to provide detailed LCI and make key assumptions that may be pertinent to relevant life-cycle stages; and 3) categorize the new building material from a dropdown list of existing building material categories, such as envelope materials, or to specify a new building material category by entering the name of the new category directly in the entry, as shown in Figure A6.

A3.1 DEFINE A CONTEXT FOR A MATERIAL

A system boundary past cradle to gate is best defined in the context of a specific building project. Upon defining a system boundary larger than cradle to gate for a material, a button will be added to optionally copy the LCA for a material and rename it in context of a specific building added to the Building Info list (See Section B2.1). Upon choosing to define the material in context of a building, the LCI for the material will be duplicated to a new material profile, renamed to detail the building the material is defined in context of.

A4 BUILDING MATERIAL TIME SERIES MODELING

The building material LCA is equipped to handle time series modeling of different materials. Time series modeling is split into two different components; the modeling year of the material currently being modeled, and the modeling year of each individual component of a material being modeled. The modeling year of a material is used to determine what year of data is saved. A material can have multiple different LCProfiles, spread across multiple years. To change the year a material is modeled in, click the “Set Modeling Year” button located under component properties

A1+A2+A3: User Manual Entry

FIGURE A8: The Set Modeling Year button, used to change the year a material is being

Modeling Year ✕

Please enter the year for modeling data

modeled in.

FIGURE A9: The User form to Enter the new Modeling Year for a material.

When the modeling year is changed, a prompt will allow the User to copy the LCI data from the previous modeling year to the new one. This will duplicate the LCI data from the original modeling year and copy it to the new modeling year. This will replace any LCI data in the new modeling year.

Confirmation ✕

Do you want to copy data from the previous year to the new year?

Figure A10: The Prompt to Copy data from the previous modeling year to the new modeling year.

When entering LCI information for a material, the user can specify the year of data used. This allows the user to use data from one year in modeling a material in a different material. For example, a material can be modeled in 2030, using component data modeled in 2020. If data is specified to be used for a material that does not have data for the specified year, a data gap will be flagged. Please see section A7 for more information on data gaps, and how to resolve them.

A5 ENTER LIFE CYCLE INVENTORY DATA AND MAKE KEY ASSUMPTIONS

It is critical to enter detailed LCI data and make key LCA modeling assumptions, such as co-product handling methods, loss factors across the supply chain, non-combustion or fugitive emissions, etc., which may be relevant to the material being modeled, for meaningful LCA modeling. This can be accomplished by entering energy and material inputs and outputs data and making assumptions with each of the life cycle stages according to the defined system boundary and functional unit. Figure A11 shows the GUI that assists the user with providing the complete, streamlined, and interconnected data required to model the embodied GHG emissions and energy impacts of a new building material.

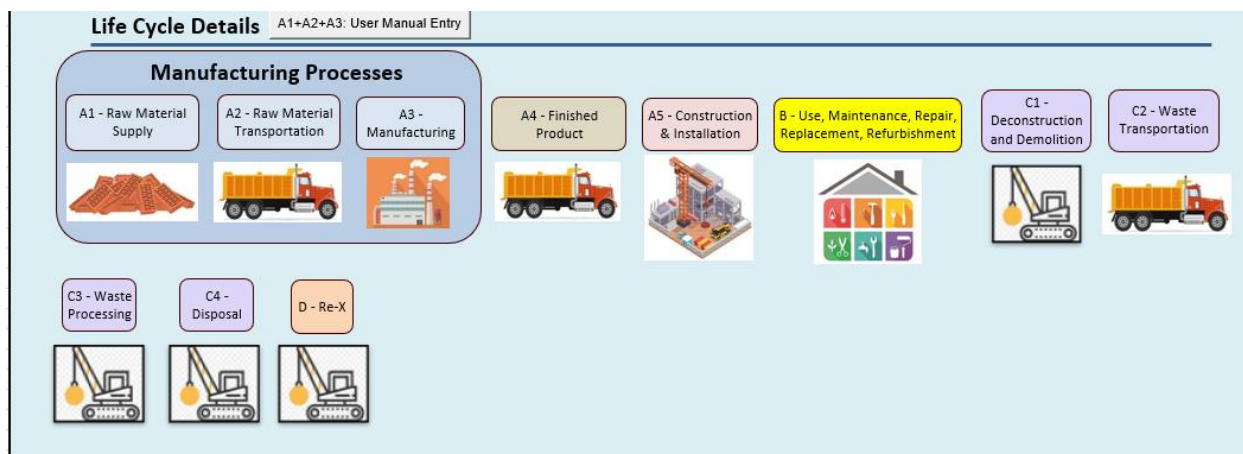

FIGURE A11: The life cycle stages of the selected system boundary to take detailed LCI data and make assumptions

A5.1 Cradle-to-Gate (A1-A3) Data Entries

For a Cradle-to-Gate system boundary, the user needs to specify the A1-A3 stages that conform to the EN-15978 Standard with energy and material inputs required to manufacture the building material and transport it to the construction site. This is the most common system boundary chosen to estimate embodied GHG emissions/energy use of a building or construction material. For modeling of this system boundary, the A1 to A3 stages are key to the manufacturing of a finished product. Therefore, we bundle the A1, A2, and A3 stages in an overall “Manufacturing Processes” group to streamline the modeling process. Once the user

clicks the group, a pop-up GUI, as shown in Figure A12, will guide the user in providing the LCI data across the A1 to A3 stages.

The screenshot shows a software window titled "Enter Manufacturing Process Information...". Inside, the main heading is "1/2\" Lightweight Gypsum Board". Below this, a section labeled "Process Steps" contains a list with one item: "F 1/2\" Lightweight Gypsum Board". To the right of this list are three buttons: "Insert New" (cyan), "Remove" (red), and two arrow buttons (up and down). Below the "Process Steps" section is a larger section with three dropdown menus: "Primary Output" (set to "1/2\" Lightweight Gypsum Board"), "Functional Unit" (set to "kg"), and "Location" (set to "USA"). Under these dropdowns are three icons representing different stages: an excavator for "A1 - Raw Material Supply", a ship for "A2 - Raw Material Transport", and a factory for "A3 - Manufacturing". Below these icons is a "Notes" section with a large text area. At the bottom right of the window is a red "OK" button.

FIGURE A12: The graphical user interface for modeling the manufacturing processes.

To model complicated, potential multi-process manufacturing, we have developed a multi-process modeling approach with the capability to model each manufacturing process individually and in the order of the overall manufacturing processes. For each process, the user can model the A1 to A3 stages necessary to complete the process. Each individual manufacturing process will produce an intermediate product, which could be a required raw material input for

any of the following manufacturing processes. This approach enables a streamlined, integrative modeling experience. The user can change the order of the manufacturing processes, add and insert a new manufacturing process, and modify or remove an existing manufacturing process.

Note that the A1-A3 group button will start with specifying the final manufacturing process by default, with a process step identification as “F”. The primary output of the final manufacturing process will be the target building material that the user is modeling (see Figure A2), with a default functional unit that is defined (see Figure A3). Note that the location of the manufacturing plant can be specified at the state level or generally be noted as in the United States. This information will be used to pull relevant state-level or national-level electricity generation data to calculate the emissions impacts of the manufacturing processes.

It is recommended that the user starts with the final manufacturing process by entering LCI data for raw material supply, raw material transportation, and process energy and material requirement via the A1, A2, and A3 buttons. Then, the user can define specific upstream manufacturing processes that produce intermediate outputs that may feed into the final manufacturing process as process materials, by entering LCI data for the A1, A2, and A3 life cycle stages the same way as for the final manufacturing process. For each upstream manufacturing process, it will have a process step identification number assigned to indicate its order in the overall manufacturing processes.

For an upstream manufacturing process, the name of the primary output can be specified from the Primary Output entry. By default, it will be the same as the process name. The functional unit of an intermediate product can be specified from a dropdown list, which gives the user flexibility to address any intermediate product that may need a different functional unit from the finished product. Figure A13 shows an example where a new upstream process called “Pre-processing” can be added.

FIGURE A14: Adding a new raw material by selecting from a list of existing materials or entering a new raw material.

Then, the user can enter the quantity, unit, loss factor, urban share, and supply location directly into the entries or by selecting from a dropdown list for each raw material, as shown in Figure A11.

To enter a unit, the user can select one from a dropdown list. If the dropdown list does not contain the desired unit, the user can enter a new unit directly into the entry. If the new unit does not have a valid conversion, a warning message that no conversion factor is available to convert the new unit to the default unit of the selected material will appear, and the user will need to use a unit that can be converted to the default unit instead. See Figure A16 as an example.

FIGURE A15: The data entry form to provide detailed LCI data related to the A1 stage.

The Loss Factor entry allows the user to specify any raw material loss that might happen at the supply/sourcing stage, prior to the transportation step (A2). A non-zero loss factor will lead to more raw material by “ $\{1/(1-\text{loss factor [in \%]}-1)\} \times 100\%$ ”, which needs to be supplied/sourced so as to compensate the material loss and to meet the downstream demand.

The “Urban share” entry allows the user to specify how much of the raw material supply/sourcing activities come from municipal statistical areas.

A “Notes” section provides the user a convenient way to take notes about data sources, assumptions, or any other details that may help clarify the data entered at this stage. The data entered at this stage will be used to calculate the embodied impacts of sourcing and supplying raw materials required.

The “Year” entry allows the user to specify the year of data used for the component. By default, every component uses data for the same year that the building material is being modeled in. However, by changing the year entry, the user can change which year of data is used, to allow a component to use data from a different year than the entire material. Note that changing the year entry for a component does not change the year the LCA will be run in, i.e. modeling a

material in 2030 while using a component with data from 2020 will still save the results in 2030, not 2020.

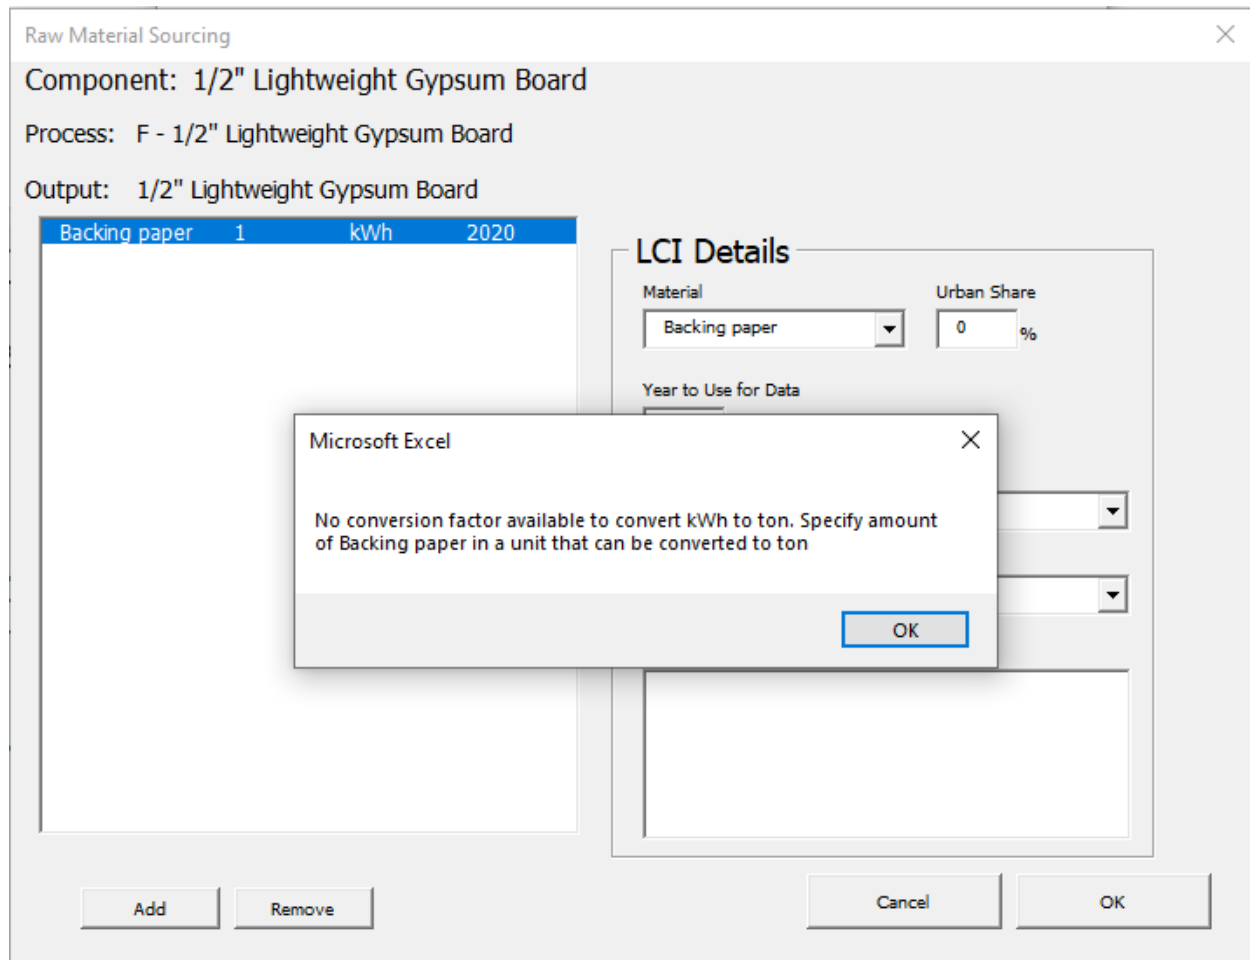

FIGURE A16: The warning message to specify a unit that can be converted to the default unit of a raw material.

Note that any entered data will be saved to the LCI database when the user clicks the “OK” button in the bottom right of the data entry form. No data that has been entered to the form will be saved if the user clicks the “Cancel” button or clicks the close the window button in the top right corner of the form.

Note that if the user enters a new raw material that does not exist in the dropdown list, this will be flagged as a data gap when the user proceeds to run the simulation, or when the user clicks the Address Data Gaps button to check potential data gaps. It is always recommended that efforts be made to address data gaps before running the simulations to generate LCA results for a building material. Ignoring any data gaps that may be associated with modeling a building material will not stop the program from running the simulation and generating results. In this case, the data gaps, as well as their associated embodied impacts, are simply ignored, leading to incomplete LCA results. This gives the user flexibility to proceed and generate results with the

best data available and the flexibility to decide when and how to address the data gaps when further information becomes available. We discuss approaches designed in the GREET Building Module to addressing data gaps in Section B4.

A5.3 Data Entries for A2

In the A2 stage, or Raw Material Transportation stage, the user enters the raw transportation related data, including the transportation distance, payload, urban share, and fuel type by transportation mode, for each of the raw materials that are specified in the A1 stage. Figure A13 shows the data entry form used to specify detailed transportation information required to model the embodied impacts at this stage. For each raw material, four transportation modes can be considered: Class 8 heavy-duty truck, rail, barge, or ocean tanker. For each transportation mode, the default information on the payload and urban share from GREET1 is used and set by default. By default, for example, the fuel type of the truck is petroleum diesel. A list of alternative transportation fuel options, for example, renewable diesel, is available for consideration. The user can make changes to the default assumptions regarding payload and fuel type to reflect the actual situation of the transportation. Besides the default assumptions, the transportation distance is a required input for at least one of the transportation modes to complete the setup of the raw material transportation modeling.

Note that the Loss Factor entry allows the user to specify any raw material loss that might happen at the transportation stage. A non-zero loss factor will lead to more raw material by “ $\{1/(1-\text{loss factor [in \%]}-1)\} \times 100\%$ ”, which needs to be transported to the manufacturing plant to compensate the material loss during the transportation and to meet the manufacturing demand.

Similar to the A1 stage, a “Notes” section provides the user a convenient way to take notes about data sources, assumptions, or any other details that may help clarify the data entered at this stage.

FIGURE A18: The data entry form to enter detailed information related to a specific manufacturing process

For each process energy input except for electricity, the user will be prompted with a new data entry form, as shown in Figure A15, to define the combustion technologies and relative combustion shares associated with using the process energy type. The relevant emission factors from GREET1 will be used to calculate the direct emissions from the using process energy via various combustion technologies, such as a boiler, turbine, engine, kiln, among others. For electricity, the electricity mix as the user defined in the overall Manufacturing Processes step will determine which specific local electricity generation mix and the associated life-cycle energy and emissions profiles will be used in the modeling. Additionally, a custom electricity generation mix can be defined at this step. For more information, see section A6.

Besides process energy inputs, the user can also specify process material inputs. Note that the process material inputs at this step do not require off-site transportation, which is different from those specified at the A1 step. This option offers the user to specify any on-site material inputs, such as intermediate products from previous manufacturing processes, that can feed into the current process to make other intermediate products or the finished product. Like the raw material entries in A1, any new process materials specified that are currently not available in the dropdown list, will be flagged as a data gap, which can be addressed separately. In addition, a data validation feature is implemented with regard to the unit entry, which will provide a warning message and guidance to specify an appropriate unit that can be converted to the default unit of a selected material that exists in the default database, as shown in Figure A19.

Any entered data can be edited or removed from the corresponding buttons to the right of the form (see Figure A18).

FIGURE A18: The data entry form to specify process energy and material inputs, as well as water consumption associated with a manufacturing process.

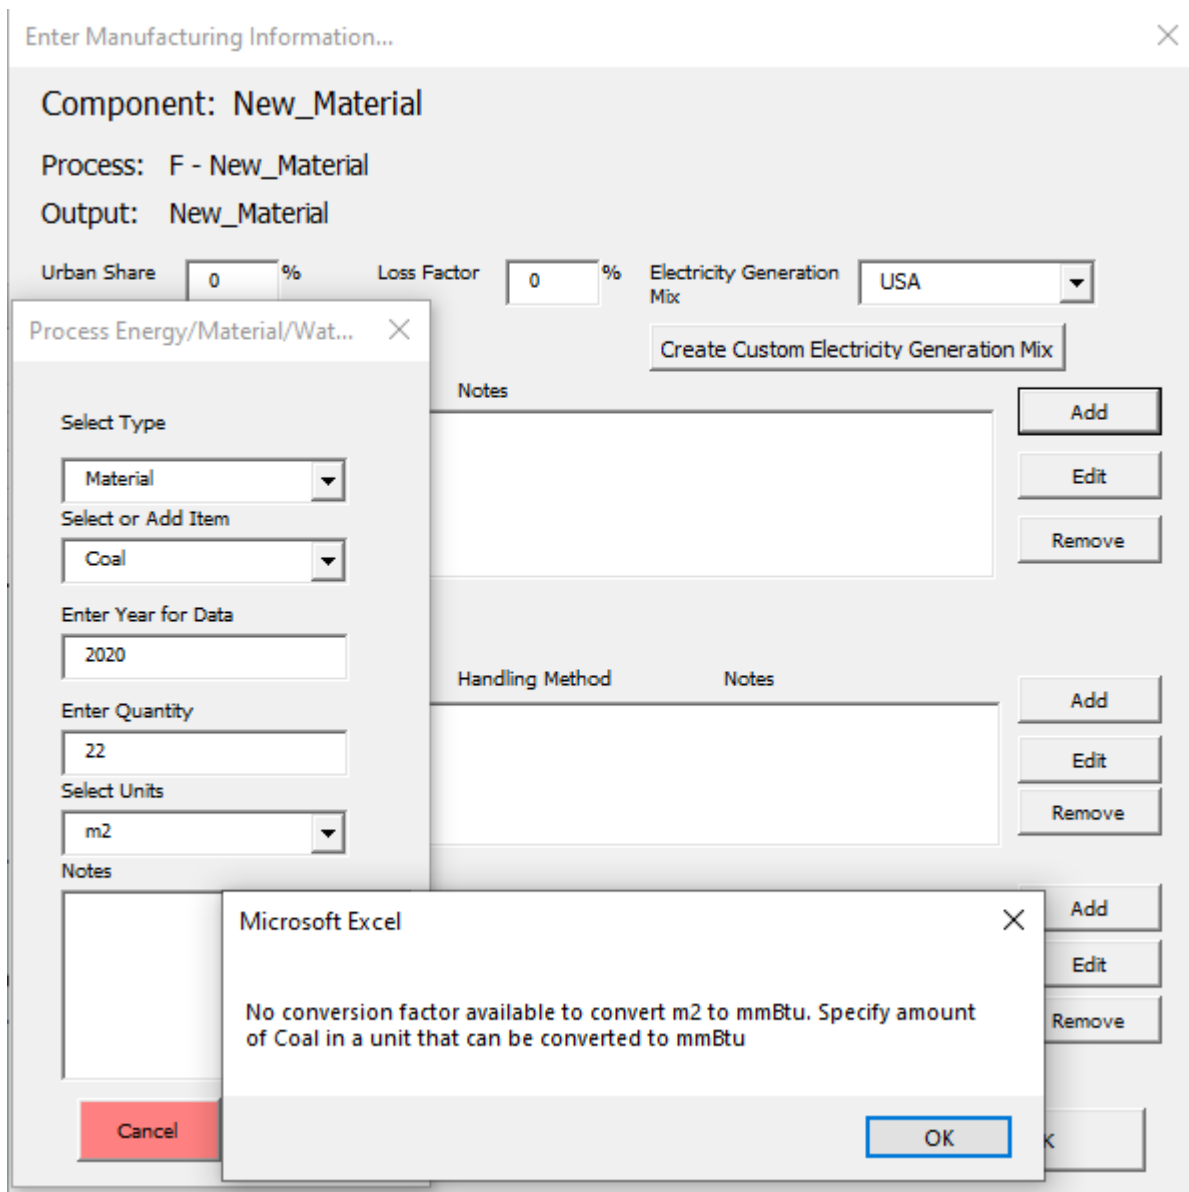

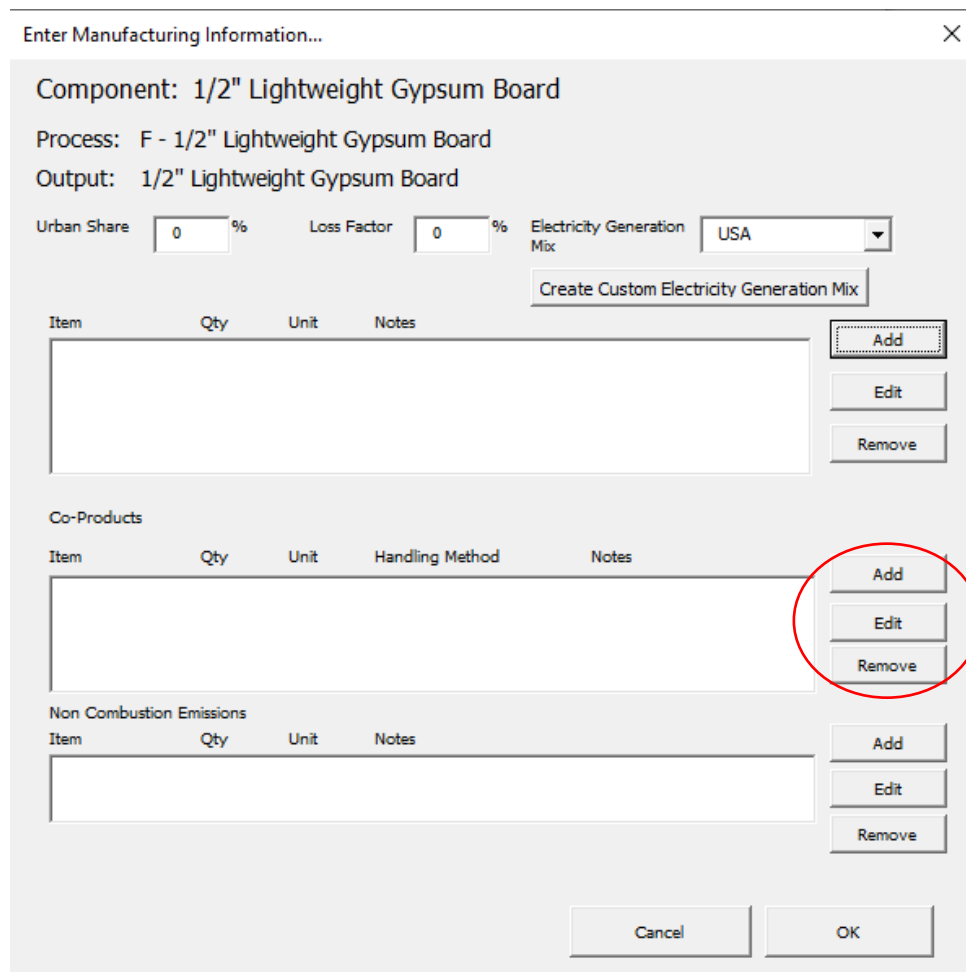

FIGURE A19: The warning message and guidance to specify an appropriate unit for a selected process material.

A unique modeling issue related to LCA in general, and one that may apply to building material LCA, as well, is to address the embodied impacts of co-products that may be present at the manufacturing stage. To begin, the user can click the “Add” button in the “Co-Products” panel of the A3 data entry form, as shown in Figure A20, and a data entry form to specify the name, quantity, unit, and handling method of co-products will open, as shown in Figure A21.

To add a co-product, either select one from the dropdown list or enter a new one if it is not available in the dropdown list. To specify the quantity and the associated unit, enter the quantity with a number and select a unit from the dropdown list. The same data validation

feature with regard to the unit selection will apply here to ensure meaningful unit selection (see Figure A16). Use the “Notes” section to add any notes regarding the data entries. Finally, a co-product handling method can be chosen from a list of four options: 1) the displacement method. When this method is selected, a product that is displaced by the co-product needs to be specified from the “Product Displaced” data entry, together with a displacement ratio, which is set to be 100% by default, as shown in Figure A19; 2) an energy-based allocation method. When this method is selected, the energy-based relative share of the co-product out of the total product slate needs to be specified, as shown in Figure A20; 3) a market value-based allocation method. When this method is selected, the market value-based relative share of the co-product out of the total product slate needs to be specified; and 4) a mass-based allocation method. When this method is selected, the mass-based relative share of the co-product out of the total product slate needs to be specified. For the methodological implications of these co-product handling methods, see Want et al. (2011) and Cai et al. (2018).

Another issue that could have significant impact on the embodied impact of a building material is to include any non-combustion related emissions, e.g., evaporative VOC emissions from use of solvent. Figure A24 shows the data entry form for specifying the type and quantity of any non-combustion GHG or criteria air pollutant emissions.

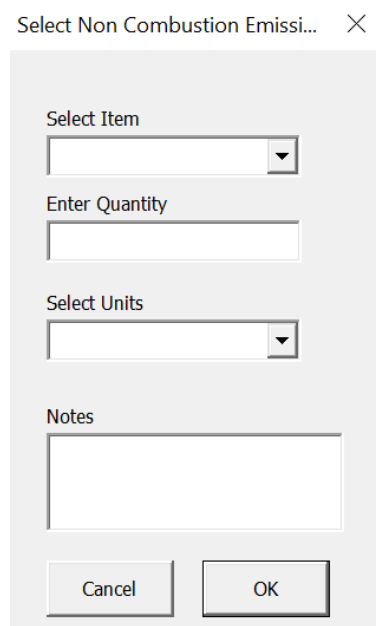

The image shows a software dialog box titled "Select Non Combustion Emission...". Inside the dialog, there are four main input areas: a "Select Item" dropdown menu, an "Enter Quantity" text input field, a "Select Units" dropdown menu, and a "Notes" text area. At the bottom of the dialog, there are two buttons: "Cancel" and "OK". The dialog box has a standard Windows-style title bar with a close button (X) in the top right corner.

FIGURE A24: Data entry form to specify the type, quantity, and unit of non-combustion emissions, if any, during the manufacturing stage.

By now, the user will have completed data entries for A1, A2, and A3 for a given manufacturing process. The user can add additional manufacturing processes by repeating these steps until all the manufacturing processes related to producing the target building material are specified.

A5.5 Data Entries for A4

In the A4 stage, or the Finished Product Transportation stage, the user will enter related data, including the transportation distance, payload, urban share, and fuel type by transportation mode, for the finished product. Figure A25 shows the data entry form to specify detailed transportation information required to model the embodied impacts at this stage. Note that if the functional unit of the finished product as the user defined (see Figure A3) is not mass based, the data entry form will ask the user to specify the weight and the unit of the weight per the functional unit defined for the finished product. The Module will calculate the transportation related impacts the same as the calculations for the A2 stage.

A5.6 Data Entries to Model Construction and Installation, Use Phase, End-of-Life, and Recycling

To model the emissions, energy, and water consumption impacts during the use phase, end-of-life, and recycling related practices and activities, the user can go to the BC Analysis worksheet, and click the relevant buttons, as shown in Figure A49. These life cycle stages include A5 – Construction & Installation, B – Use, Maintenance, Repair, Replacement, Refurbishment, C1 – Deconstruction & Demolition, C2 – Waste Transportation, C3 – Waste Processing, C4 – Disposal, and D – Re-X. Stages A5, B, C1, C3, and D have data entered in the same fashion as done in A3. The C2 stage represents the transportation of waste products during the end of life of the building material, and data is entered in the same manner as described in stages A2 and A4.

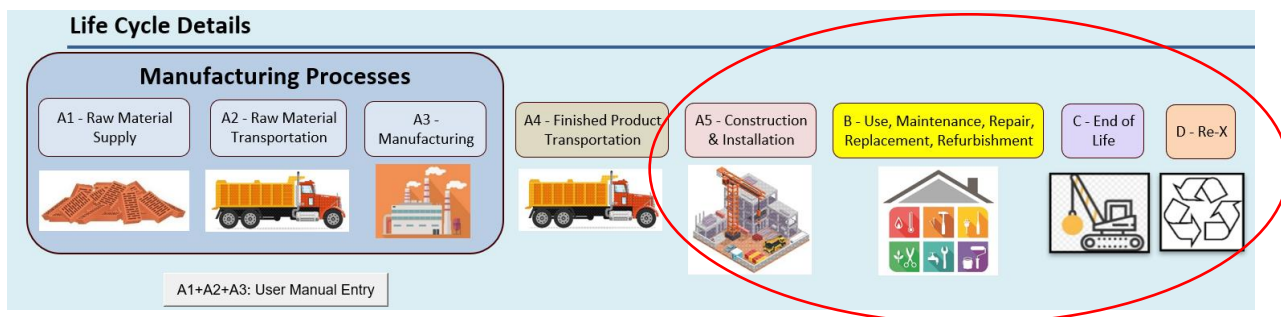

FIGURE A49: Interactive buttons in the BC Analysis worksheet to take data entries for modeling construction and installation (A5), use phase (B-stages), end-of-life (C1, C2, C3, and C4 Stages) and recycling/remanufacturing/reuse practices (D-stages).

For each of these life cycle stages, the corresponding button will open a generic data entry form that has the same data placeholders for entering direct process energy and material inputs, co-products related information, and any non-combustion emissions associated with activities and practices that take place at that stage.

As the system boundary expands from the Cradle-to-Gate stages, new LCA issues may require new LCA methodology, modeling capabilities and features to fully address in an integrated fashion. For example, replacement of a building material during the use phase may require a different functional unit from the one defined to address the Cradle-to-Gate impacts, which is beyond the current modeling capabilities that focus on a streamlined, integrated modeling approach in the BC Analysis modeling platform. However, direct impacts arising from any direct energy and material consumptions to complete the building material replacement can be modeled. The BC Analysis modeling platform is also capable of modeling direct impacts associated with other use phase operations, such as maintenance, end-of-life activities such as landfilling, as well as machinery operations and/or remanufacturing processes that may be required to complete the recycling and remanufacturing activities. In addition, similar to typical process-level LCA that focus on direct impacts associated with material and energy inputs and outputs, consequential impacts of certain life cycle stages, such as emissions and potential carbon sequestration impacts of landfilling, may require separate modeling platforms to address. As LCA methodology and data required to address such challenging issues evolve, Argonne will expand the GREET Building Module with additional modeling capabilities and features to address such issues and potential consequential impacts.

A6 DEFINING A CUSTOM ELECTRICITY GENERATION MIX

The GREET Building Module is equipped to allow the user to generate a custom electricity mix, by first defining a generation mix across common electricity generation sources, and then connecting with GREET 1 to generate life cycle data for the customized generation mix. This feature requires the user to also have GREET 1, and for the user to specify the filepath and file name of the GREET 1 file within the ModelSetupInfo worksheet. The file path and file name cells are located at cells X2 and Y2, respectively, as shown in Figure A26. The file path must

contain the full file path, not including the file name of the GREET 1 file, and the file name must include the full name of the GREET 1 file.

X	Y
GREET1 FilePath	GREET1 FileName
Full File Path Not Including File Name	File Name

FIGURE A26: The cells containing the GREET 1 file path and file name, located on the ModelSetupInfo worksheet.

A custom electricity generation mix can be defined for use in either the building material LCA or whole building LCA. For use in building material LCA, this feature can be accessed from the Create Custom Electricity Generation Mix, located on the user form for the A3 stage, as well as all life cycle stages past the cradle to gate boundary. For use in whole building LCA, it can be accessed with the Generation Custom Electricity Mix button located on the Whole Building LCA worksheet. These buttons are shown in Figures A27 and A28.

FIGURE A27: The Create Custom Electricity Mix button, used to generate custom electricity mixes used in Building Component LCA.

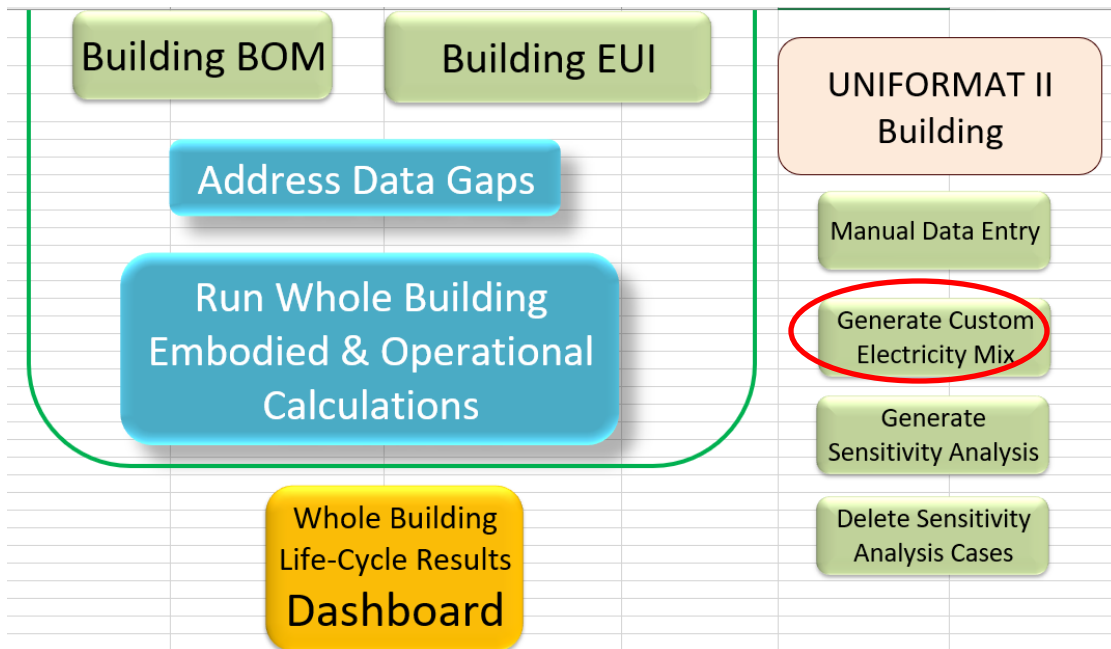

FIGURE A28: The Generate Custom Electricity mix, used to generate custom electricity mixes used for Whole Building LCA.

Note that a custom electricity generation mix will only be usable for the material selected in Building Component Analysis, or for a selected building. For Whole Building LCA, the user can specify whether the custom electricity mix should be usable in all Whole Building Analysis, or only for a specific building.

FIGURE A29: The user form to select which building to generate a custom electricity mix form. The user can specify a building from the dropdown list or allow the custom electricity generation mix to be usable for all Whole Building Analysis.

Upon clicking the Load Custom Mix Generation Form button on the above user form or clicking the Create Custom Electricity Generation Mix button located in the building component analysis user forms, a user form will appear to guide the user through the process of creating a

custom electricity generation mix, shown in Figure A30. To enter generation data, the user enters the use percentage of residual oil, natural gas, coal, nuclear power, biomass, and other generation sources. For other generation sources, the “Others” category is further broken down into several common electricity sources including hydroelectric, geothermal, wind, and solar, while also including a further “Others” category to include all sources of electricity generation not specified above. In addition, the user can specify the electricity transmission and distribution loss associated with the custom generation mix.

For whole building LCA, by default, a custom generation mix will keep the same electricity mix from 2020 to 2080. However, the user can specify time series results to alter the generation mix from year to year. Note that the custom generation mix will always have data for every year from 2020 to 2080; the time series feature allows the user to change the generation mix breakdown from year to year. Even if the generation mix breakdown is kept the same, the life cycle results could change over time due to changes in the background data over time found in GREET 1. To activate, the user clicks the “Generate Time Series Results” option at the bottom of the user form. This expands the user form, allowing the user to view and change the generation mix across years, shown in Figure A31. The data preview in the top right of the form allows the user to see the breakdown of the electricity generation mix for every year from 2000 to 2080. The “Years to add Generation Mix To” textboxes allow the user to specify a range of years the currently entered generation mix should be applied to. A starting and ending year, inclusive, are added to each textbox respectively, and the Add Generation Mix to Selected Year Range button clicked to add the generation mix to the range of years. To add a generation mix to one year, the user clicks the desired year within the data preview window, and clicks the Add Generation Mix to Selected Year button. The Copy Generation Mix from Selected Year button allows the user to first click a year of data within the data preview window, then click the button to copy the generation mix to the text boxes on the left. This function allows the user to copy a generation mix entered in one year to one or more additional years.

When the user has specified the generation mix, the Create Generation Mix button will initialize the process of creating the electricity generation life cycle data. Please note that this process could take several minutes, during which Excel will be unresponsive. The generated electricity life cycle data can then be viewed in the GREET 1 Time Series worksheet in the GREET Building Module, and the generation mix breakdown can be viewed in the Custom Electricity Mix. Afterwards, the generation mix can be used for the building material selected during the initial process in BC Analysis, or the building(s) selected in the initial Whole Building Analysis process.

A7 ADDRESS DATA GAPS

As noted in the A1 and A3 data entry stages, a data gap will be detected if a newly entered material is not available in the default life-cycle profile database (located in the LCProfiles worksheet). To address a data gap, the user has 4 options: 1) using the life-cycle profile of a material that is available from the default life-cycle profile database as a surrogate; 2) specifying a customized life-cycle profile, possibly from literature; 3) using a life-cycle profile of the same material modeled for a different year; and 4) generating the life-cycle profile of a data gap based on detailed, process-level data and modeling following the steps detailed in Section 1.3. There are two buttons available for listing and addressing data gaps: the “Address Data Gaps” button

provides a user form for addressing data gaps found in the currently selected building material, while the “Address all Gaps” button provides a user form for addressing any material that is a data gap in the current modeling year.

Note that the list of data gaps for the current material is also shown on the BC Analysis interface, shown in Figure A34. This list shows the list of data gaps in the material, what year of data is intended to use for the material, and what years of data (if any) are available.

Upon clicking the Address Data Gaps button, a user form will appear to guide the user through resolving data gaps. This userform is shown as figure A32. The listbox in the userforms shows what materials are data gaps for the selected building material, as well as what year the data is being modeled in, and what alternate year(s) of data are available. The Select Alternate Modeling Year button allows the user to switch what year of data is used for a component. The “Use Closest Available Year for All Gaps” button allows the user to select the closest year with available data for each component. The “Resolve Data Gap” button allows the user to resolve a gap through modeling the gap, selecting a surrogate, or manually providing the life cycle data. To resolve a gap, click on the item in the list. Then, the user can either choose to switch the year of data, or resolve the gap through one of the other three methods listed above. See figure A33 for the userform for switching the year of a data gap.

Data Gaps In Selected Model	Year being Modeled	Years of Data Available

HBCD flame retardant	2020	

Resolve Data Gap Select Alternate Modeling Year Use Closest Available year for ALL Gaps

FIGURE A32: The user form for resolving data gaps for a selected building material.

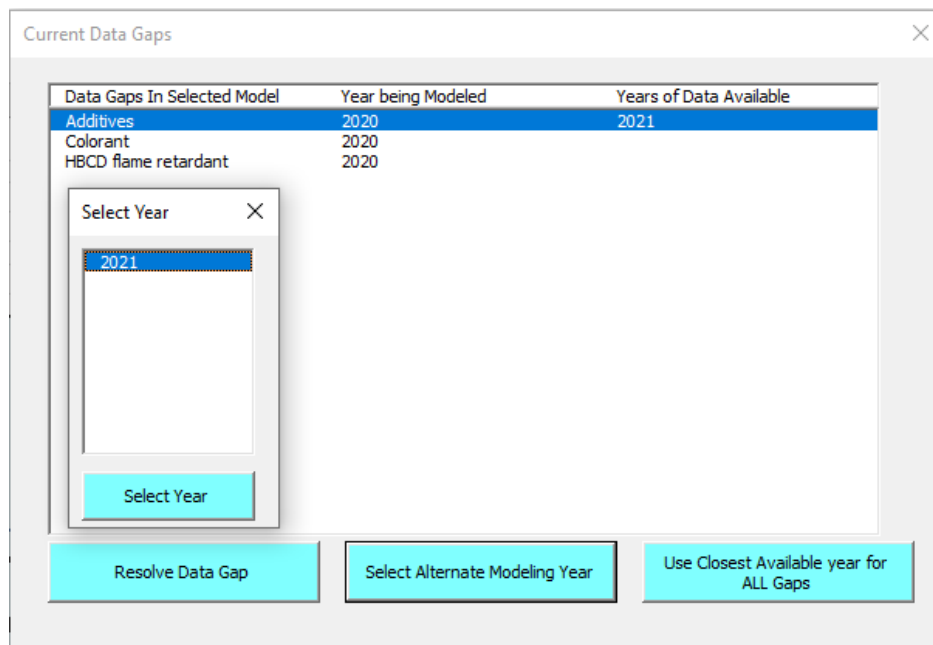

FIGURE A33: Selecting to use data modeled in 2021 for Additives, a component of the selected building material.

To address the list of all data gaps, click the “Address All Data Gaps” button. Figure A35 shows a list of data gaps that are identified and remaining for a range of building materials included in the GREET Building Module, after clicking the “Address Data Gaps” button in green, located in the BC Analysis worksheet. A list of data gaps that are identified and addressed can be accessible in the “Resolved Gaps” category. To address a data gap shown in the remaining data gap list, double click to open up the three options available, as shown in Figure A36.

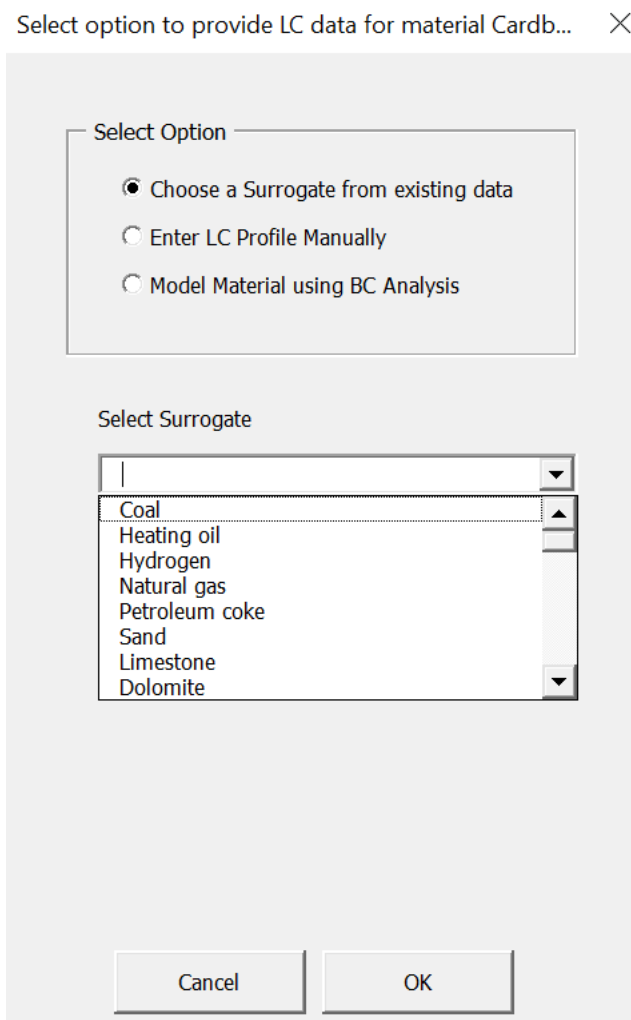

FIGURE A37: Address a data gap by selecting a material from a list of existing materials in the background database as a surrogate.

When the “Enter LC Profile Manually” option is selected, enter the life cycle results metrics for the material manually, as shown in Figure A38.

When the “Model Material using BC Analysis” option is selected, the user will be taken to the BC Analysis worksheet to conduct a process-level, detailed LCA following the steps given in Section A1.3, together with a message window about this overall procedure, as shown in Figure A39. After clicking “OK” to close the message window, the user can start to enter detailed LCI across the supply chain of the gap material before clicking the “Run Simulation” button to generate the LCA results for the gap material, which will be saved and added to the background LCProfiles database, with a comment noting that this is “User Modeled Data”. This note provides information on the data source and will be used to filter materials by data source when considered in a whole building design in the whole building LCA, which is detailed in Section B.

A8 RUN SIMULATION TO GENERATE LCA RESULTS

After entering LCI data across the life cycle stages for a given system boundary, the user can run a simulation to generate LCA results by clicking the “Run Simulation” button in the BC Analysis worksheet. Note that the data gap detection and addressing feature described in Section A7 is baked into this step, which automatically detects if there are any data gaps that could be addressed before proceeding to run the simulation. If any data gaps are detected, a message window will pop up, as shown in Figure A40, to remind the user of the issue. The user can decide whether to ignore any data gaps or address them. Proceeding with the simulation without addressing the data gaps will generate somewhat incomplete results, without accounting for the impacts of the gap materials. Again, this simulation procedure gives the user flexibility to proceed and generate results with the best data available, especially when the data gaps account for a small fraction of the bill of materials and thus might have a small impact on the simulation results. Meanwhile, the data gaps detected will be listed in the “Data Gaps in Selected Model” block. Later, when the user selects the same building material from the BC Analysis GUI, the data gaps that have been detected previously will show up in the “Data Gaps in Selected Model” block, reminding the user to address them when further data and information become available.

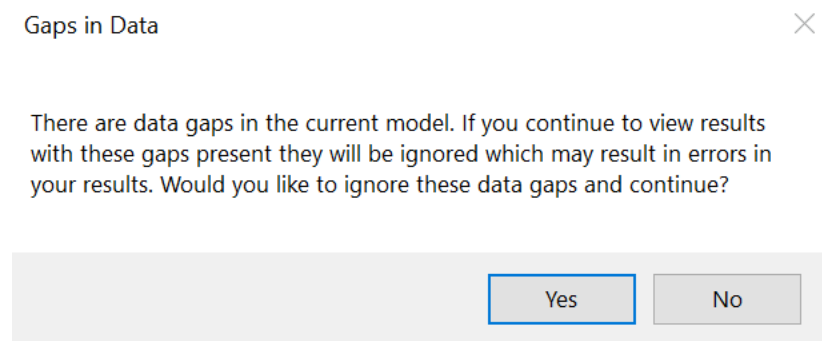

FIGURE A40: The message window warning the user of gaps detected before running the simulation

When no data gaps are detected after clicking the “Run Simulation” button, the program will proceed to calculate and generate the LCA results. A progress bar will pop up, showing the real-time progress of running the simulation, as shown in Figure A41. Depending on the number of data records that are involved with a simulation, it could take from seconds to minutes to complete the simulation.

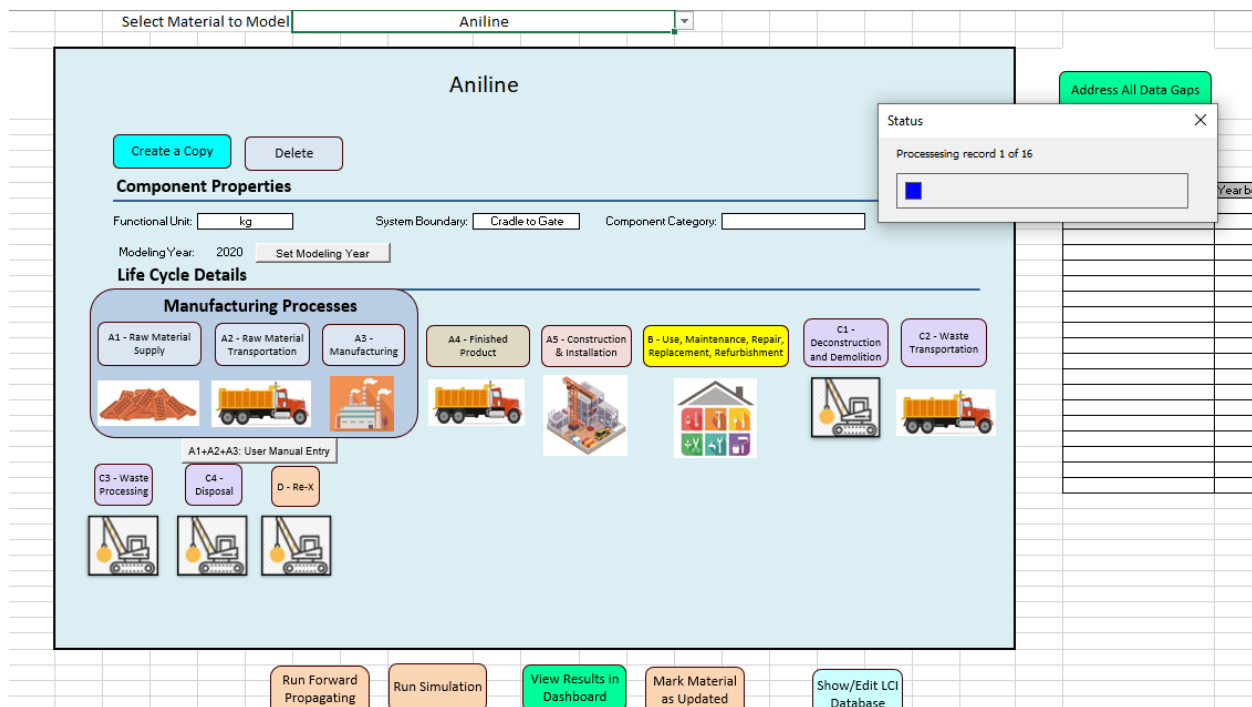

FIGURE A41: A progress bar showing the real-time progress of running the simulation.

A9 FORWARD AND BACKWARDS RECURSIVE LCA

In addition to running the Building Component Life Cycle Analysis normally, the user can also select to run a forward or backwards running recursive LCA by clicking the relevant buttons on the BC Analysis worksheet, shown in Figure A1.

A9.1 Backwards Recursive LCA

Backwards recursive LCA is designed to enable a streamlined update of modeling the top-level material by recursively incorporating updates/changes at the sub-component level. It will first run the LCA on all subcomponents on a material, before running on the material itself. For example, if material A has subcomponents B and C, then B and C will be run through the Building Component LCA before material A is run. This process continues recursively down the entire material tree of the original building component. In the previous example, if materials D and E are subcomponents of material C, then materials D and E will be run through the LCA before material C, and material C will be run before material A. Note that this process will take considerably longer to run than the default Life Cycle Analysis, as the LCA process will have to be repeated for each subcomponent.

A9.2 Forward Recursive LCA

Forward recursive LCA is designed to enable a streamlined update of all the materials that may be affected by updates/changes of other materials or background data, in an order that

propagates the chain of causal effects starting with such updates/changes. It will allow the user to first run LCA on a selected building component(s), and then run LCA on any building component that uses the original components and any background data as inputs. For example, if material A has subcomponents B and C and if some background data that may affect subcomponent C has been updated, the user can choose to run forward recursive LCA on material A. The module will start with an update LCA on material C, then run LCA on A. Upon clicking the forward propagating LCA button, a user form will pop up to allow the user to select which materials will have the LCA run on them. To add materials, select the name in the combo box, then click the Add above material button. The list of materials which need updates can also be added by clicking the button below. Finally, a material can be removed by selecting it in the list and clicking the remove button.

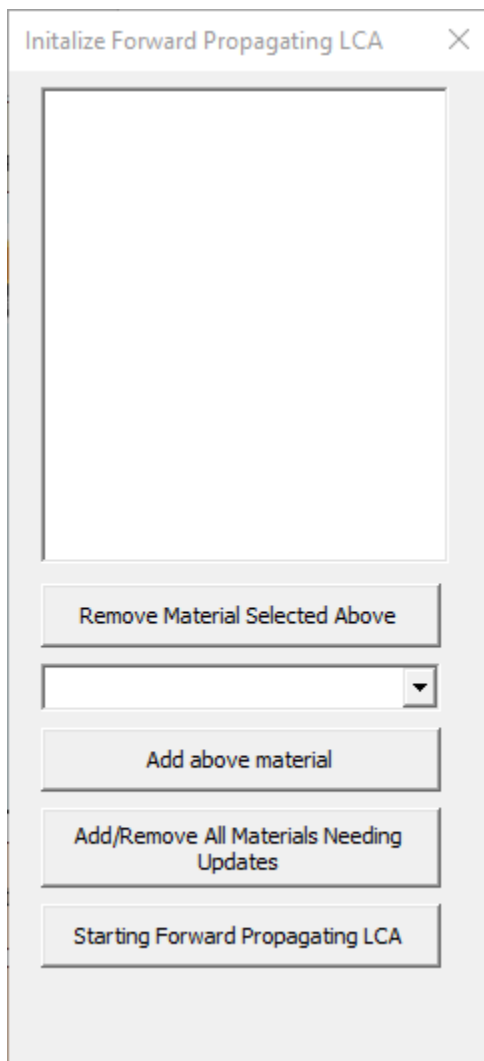

The image shows a software window titled "Initialize Forward Propagating LCA" with a close button (X) in the top right corner. The window contains a large empty rectangular box at the top. Below this box are five buttons arranged vertically: "Remove Material Selected Above", a dropdown menu, "Add above material", "Add/Remove All Materials Needing Updates", and "Starting Forward Propagating LCA".

FIGURE A43: The userform for initializing forward propagating LCA.

Next, a userform will appear to allow the user to select which materials will be run in the LCA, as shown in the userform below. Each line in the listbox shows which material will be added, and the necessary subcomponent for running that material. If a material is selected to be

run in the LCA, the relevant subcomponent must also be run. For example, in the figure below, MDI may be run without selecting Polyiso Roof, but Polyiso Roof may only be run if MDI is also run. Before finalizing the LCA, a final userform will appear to show the user which materials will be run through the LCA, and in what order.

Selection Status	Main Component to Run	SubComponent that Will be Run
Deselected	1.EIFS_Fraunhofer Prefabri	Polyiso Wall
Deselected	1.Vinyl siding_Fraunhofer P	Polyiso Wall
Deselected	2.ORNL Modular Overclad t	Polyiso Wall
Deselected	5.Syracuse Integrated Who	Closed-cell spray polyureth
Deselected	Closed-cell spray polyureth	MDI

Deselected	Polyiso Roof	MDI
Selected	Polyiso Wall	MDI
Deselected	Polyurethane rigid foam	MDI

Buttons at the bottom: Select/Deselect All, Cancel without saving, Run Forward Propagating LCA

FIGURE A44: The user form for finalizing what materials are run through the forward propagating LCA.

The image shows a 'Confirm Running LCA' dialog box. At the top, there is a title bar with the text 'Confirm Running LCA' and a close button (X). Below the title bar is a list box with the heading 'Material to be Run'. The list box contains three items: 'Aniline', 'MDI', and 'Polyiso Wall'. Below the list box, there are two buttons: 'Run Forward Propagating LCA' and 'Cancel'.

FIGURE A45: The final user form confirming what materials will be run through the forward propagating LCA, and in what order.

A10 VIEW AND EXPLORE LIFE CYCLE RESULTS

After a simulation is completed, the user can click the “View Results in Dashboard” button in green, located in the BC Analysis worksheet, to view and explore details of the LCA results in a dynamic Dashboard.

On the Dashboard, the LCA results are broken into two categories. First, the embodied GHG emissions or other embodied impact metrics, such as embodied fossil energy consumption, embodied water consumption, etc., are visualized in dynamic PivotCharts; Second, a table of LCA results across the life-cycle stages of the last building material that is modeled.

A10.1 View, Explore, and Compare Embodied Results with PivotCharts

The embodied GHG results are displayed as a series of PivotCharts and associated filters, or slicers, on the BC Analysis Dashboard (Figure A29). To view the results of newly modeled materials, right click the PivotChart at the top of the results display and click “Refresh” after running calculations. This will update the display to show the proper results. There are four PivotCharts set up to visualize the embodied GHG emissions, by default, across the life cycle stages, both stacked and unstacked, as well as contributions of material and energy inputs across the life cycle stages. Additionally, users can choose to select only specific building materials, life cycle stages, material and energy inputs, and life cycle metrics of interest through four groups of filters/slicers to control the PivotCharts (Figure A30). Selecting a filter/slicer button will enable

only that option to be shown on the PivotCharts. Holding the Control key and clicking multiple buttons will display all clicked options in the results. Note that any changes through the filters/slicers will change all the four preset PivotCharts as they are dynamically connected. Additionally, the user can change the unit used with each type of metric by changing the cells located at G4-I4.

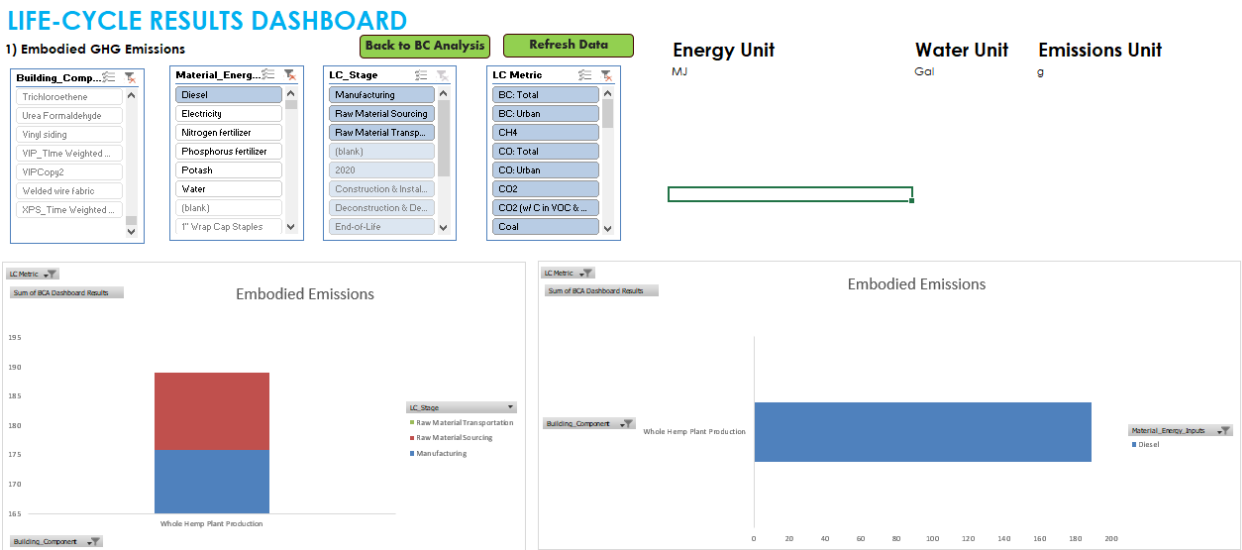

FIGURE A46: The Dashboard to view, explore, and compare embodied GHG emissions and other impact metrics of building materials through dynamic PivotCharts.

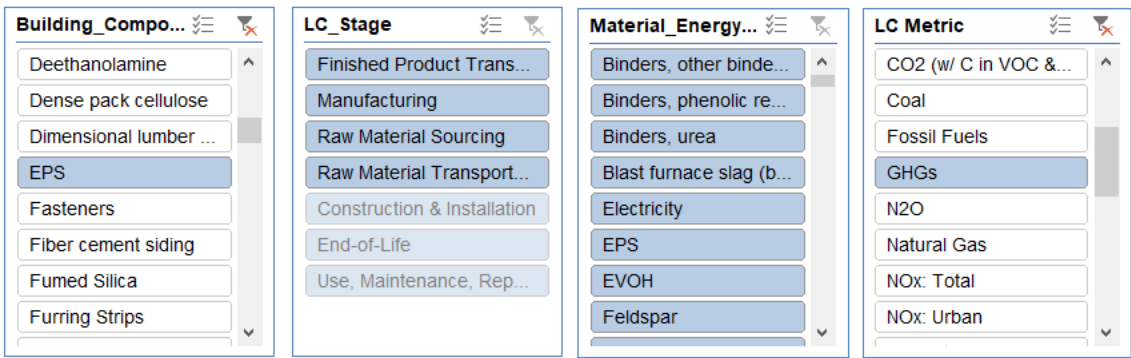

FIGURE A47: Filters/slicers that are dynamically connected to the PivotCharts to control contents to view and compare among building materials.

A10.2View Numerical Embodied Results

A summary table of LCA results across life cycle stages for embodied GHG emissions, as well as a range of other impact metrics encompassing embodied energy consumption, water consumption, and criteria air pollutant emissions, is available for the last building material that

[illegible]

A12 CREATE A COPY OR DELETE RECORDS OF EXISTING BUILDING MATERIALS

49

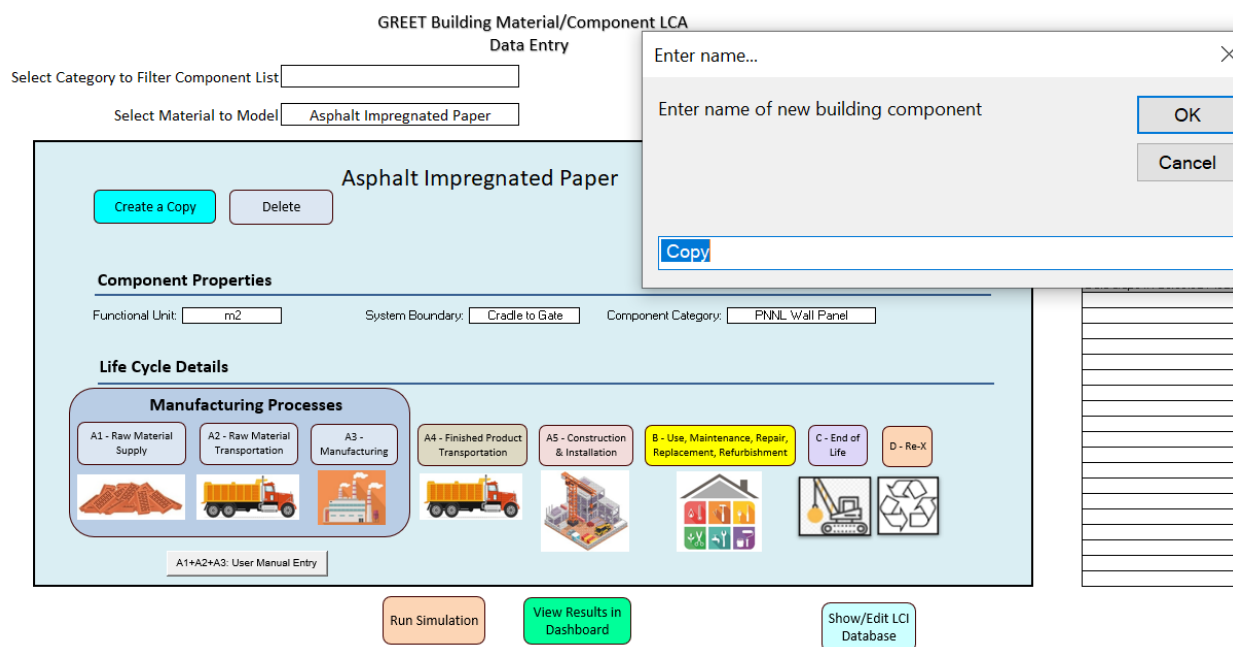

FIGURE A50: Name a new building material that is a copy of an existing building material.

To delete a building material from the Module, select it from the “Select Material to Model” dropdown list located at the BC Analysis worksheet and click the “Delete” button in the building material LCA GUI. A message window will pop up to confirm the operation, as shown in Figure A51. Note that the data and record removed from this operation are irreversible.

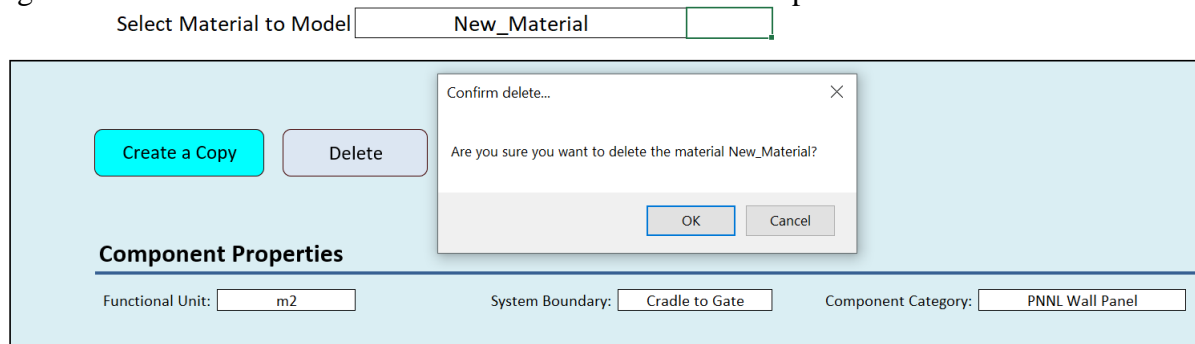

FIGURE A51: Delete a building material.

A12.1 Add Cradle-to-Gate Data Manually

To include LCA results that are reported in literature and open sources for further analysis beyond the system boundary and for whole building LCA as additional data sources, the GREET Building Module allows manual entries of Cradle-to-Gate (from A1 to A3) embodied results. To do so, the user can click the “A1+A2+A3: User Manual Entry” button located at the BC Analysis worksheet, and enter the data, including the functional unit, using a data entry form

shown in Figure A52. The user can also make notes about details, such as data sources, key assumptions, limitations, etc., of the data.

The data added will be saved to the LCProfiles database, serving as a new data source for a building material that may be considered for a whole building design and LCA modeling. It also serves as the basis for extending the analysis of that building materials from the Cradle-to-Gate system boundary to including other impacts during use phase, end-of-life-, and/or recycling, remanufacturing, and reuse scenarios.

FIGURE A52: The data entry form to add Cradle-to-Gate results from literature manually.

A13 IMPORT DATA FROM ANOTHER FILE

To facilitate parallel efforts by individuals or teams, who may be using the GREET Building Module to conduct LCA of different building materials in separate, but parallel, efforts, we have included a feature to import data from another GREET Building Module working file that is in the local computer drive. To begin, click the “Import Component from Another File” button located at the BC Analysis worksheet. A warning message window, as shown in Figure A53, will pop up to remind the user to first backup the version of the GREET Building Module receiving the import data prior to importing data.

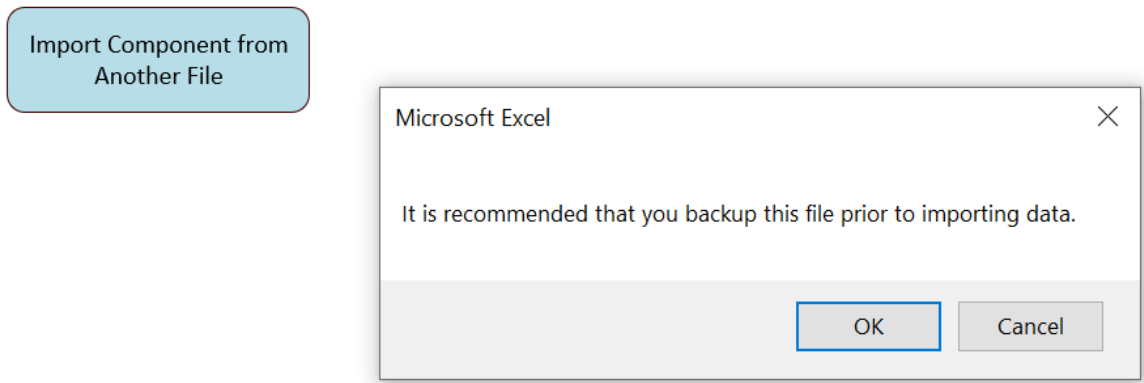

FIGURE A53: The warning message to always backup the GREET Building Module file prior to importing data from other files.

When it is ready to import data, open a different version of the GREET Building Module file to import data from, and a data import window will pop up, providing a dropdown list to select which building materials from the file to import, as shown in Figure A54. Note that when importing a building material that has the same name of another material already existing in the receiving GREET Building Module file, the import data will overwrite that of the default one, with a warning window for the user to decide on the import. The user will need to run a simulation of the imported building material to generate or update the LCA results.

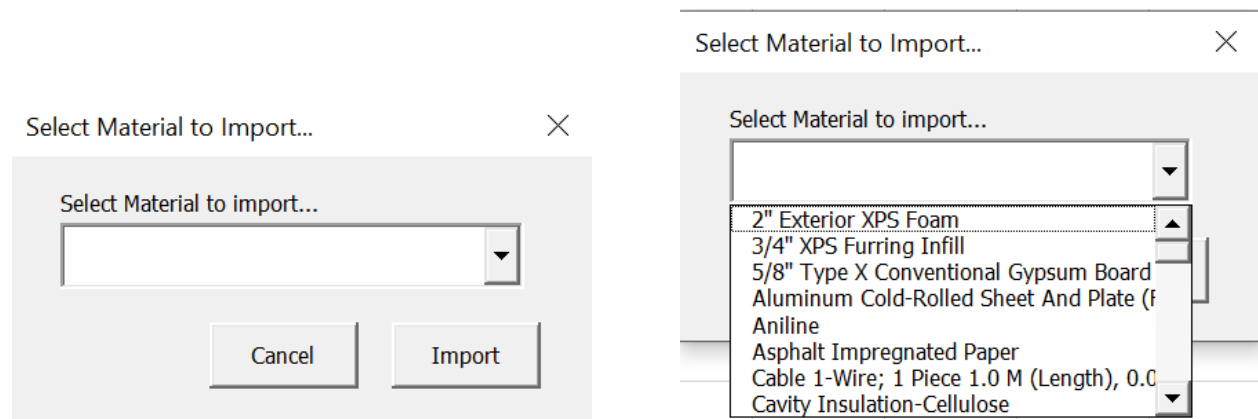

FIGURE A54: Selection of building material to import from another GREET Building Module file.

B WHOLE BUILDING MODELING

In addition to modeling individual building materials, the GREET Building Module is equipped to model embodied and operational GHG and energy impacts for a whole building or a building design. The whole building LCA modeling is broken down into three parts: 1) Information on the building, 2) Information on the Bill of Materials (BOM), and 3) operational energy consumption, or Energy Use Intensity (EUI) information. In general, these foreground data required for a whole building LCA can be entered into the Module in one of two ways. Users can interact with user interface forms designed to simplify the data entering process, or users can manually enter data into the Module directly through data worksheets. Both processes begin on the whole building LCA dashboard located at a worksheet named “Whole Building Modeling”.

B1 OVERVIEW OF THE WHOLE BUILDING LCA PLATFORM

The Whole Building LCA Platform can be found on the worksheet titled “Whole Building Modeling. There are three buttons to operate the user interfaces to enter data regarding building information, building BOM, and building EUI. A separate button to manually enter the same categories of data in three different worksheets is also available (Figure B1). After which, there are buttons to address data gaps, run the calculations, and view the results. Additionally, buttons are present to configure sensitivity analysis for Whole Building LCA, as discussed in section B5

Note that the GREET whole building LCA modeling fully incorporates the UNIFORMAT II classification for building elements and related sitework, which is detailed in ASTM Standard E1557. UNIFORMAT classification has been recommended by the Construction Specifications Institute/Construction Specifications Canada (CSI/CSC) to structure schematic phase specifications, and by the Design-Build Institute of America for performance specifications. The Standard UNIFORMAT II classification provides a common structure linking the building design, specifications, and life-cycle analysis. Its integration into the GREET whole building LCA framework enables comparability of life cycle analysis results of alternative building designs, material choices, and construction practices.

A button is available to take the user to review details of the UNIFORMAT II classification, which has three mandatory categories and a fourth tier of recommended category of building elements. For users who are not familiar with the UNIFORMAT II classification, it is recommended that he/she check the details before preparing and entering itemized BOM data that can be compatible with the UNIFORMAT II classification as much as possible.

Once the required data for embodied and operational impacts modeling are entered, a following button will allow the user to detect and address any potential data gaps by automatically checking the itemized BOM data entered against the default material/energy database located in the LCProfiles worksheet in the Module. The user will get feedback on potential gaps and guidance on how to address identified data gaps in an interactive process as

detailed below in Section B3. After that, the user can click a button to calculate the whole building embodied and operational impacts of buildings.

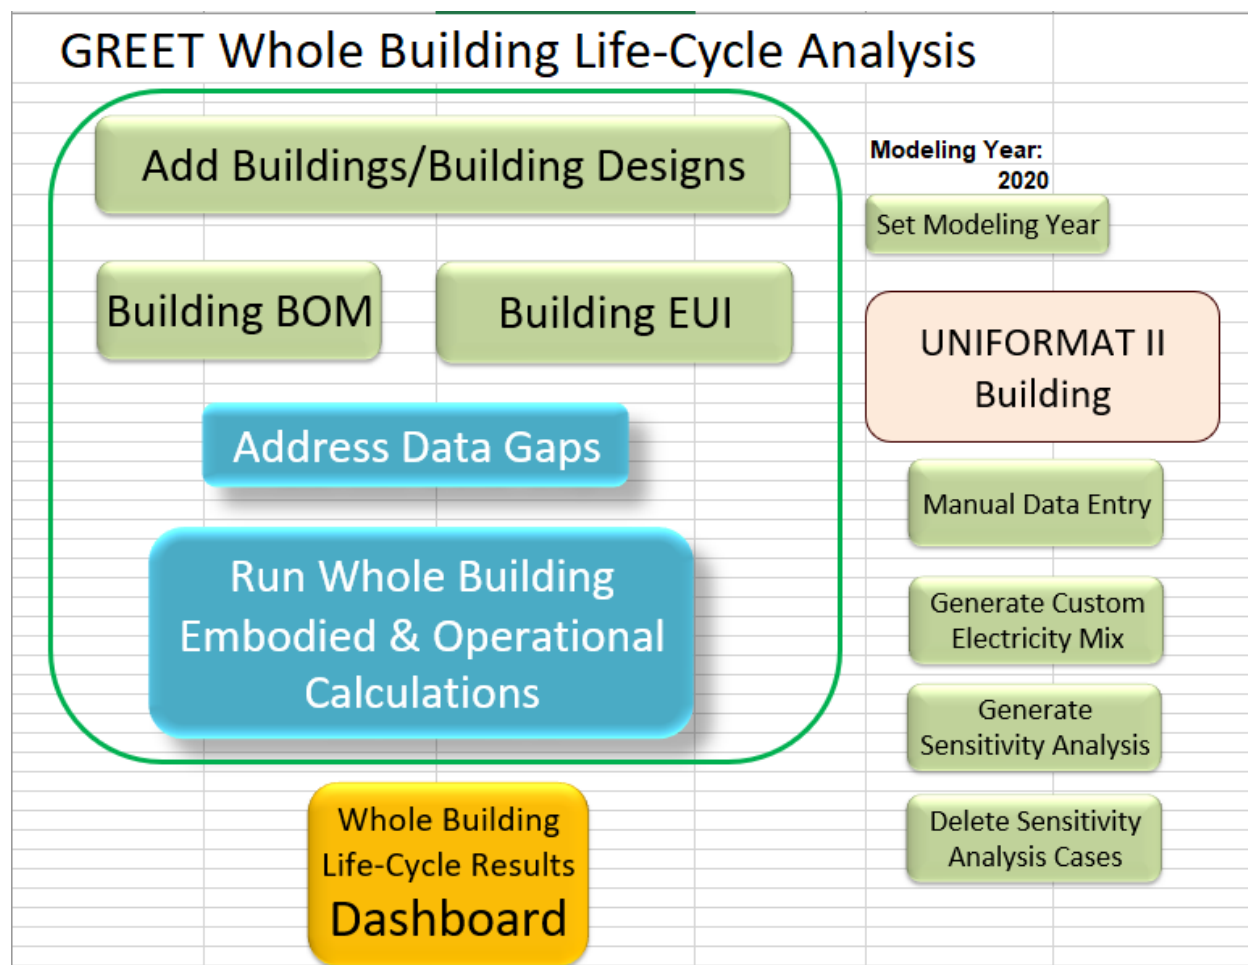

FIGURE B1: The whole building LCA modeling framework.

When the calculations are completed, the results are visualized in a Dashboard with pre-set charts that are dynamically linked to the modeling results, allowing for exploration, interpretation, and comparison of the results of selected buildings/building designs in a dynamic fashion. This dashboard can be found on the “Dashboard_WB” worksheet, accessed using the “Whole Building Life-Cycle Results” button on the Whole Building Modeling worksheet. This dashboard is described in section B7.

B2 ENTERING WHOLE BUILDING MODELING DATA

Data can be entered into the model in one of two ways. Users can enter data through a variety of user interface forms or enter data manually into the data worksheets. It is recommended for most users to interact with the user interface forms, as they simplify the

process of data entry as well as properly format the data for the model. To access the user interface forms or manually enter data, use the buttons found on the Whole Building Dashboard, described in Section B1.

B2.1 Whole Building Analysis Data Aggregation and Time Series LCA

During Whole Building Analysis, the Bill of Materials data supports data aggregated to the system boundary, or to the life cycle stage. Material life cycle data for whole building analysis is stored in the Aggregated LCProfiles worksheet. This is discussed in section D3. Before running LCA, the user will be prompted to select the system boundary for the analysis, as well as the data aggregation type; aggregated to the system boundary, or disaggregated to the life cycle stage.

Additionally, the Whole Building Analysis module is equipped with time series functionality. A modeling year can be selected from the dashboard, to allow the user to model a building starting in any year. GREET1 and GREET2 data are present, including electricity generation mixes for each U.S State and a National Average, from 2020 to 2080 to support time series modeling. Additionally, when a material is entered into the bill of materials, a replacement period can be entered. Every time the replacement period elapses, the calculation of life cycle data will use data from the relevant year. For example, a material with a replacement period of 20 years in a building with a lifespan of 60 years starting in 2020 will be modeled in 2020, 2040, 2060, and 2080.

B22 Entering data through Building Info Interface

Data is entered through the user interface forms using the buttons located on the Whole Building Dashboard (Figure B1). To begin, users enter the building information into the Building Information Interface (Figure B2). This interface is accessed by clicking the “Add Building/Building Designs” button on the Whole Building Dashboard.

Location

FIGURE B2: The Building Info Interface.

To begin entering building information, users enter data into the text boxes at the bottom of the form. The building name and building index serve as identifiers for this building. Separate building records can share the same name, or share the same index, but each building record must have a unique building name and index pairing. The lifespan of the building is entered in years and determines how many years of Energy Use Intensity information the building can have. The floor area, in square feet, is the total floor span of the building. The system boundary represents the boundary for both BOM data and EUI data. Choices range from Cradle to Gate all the way to Cradle to Cradle. The building vintage is used for retrofitting old buildings. It serves as a record of how many years the building has already been in operation. The number of floors is the total number of floors in the building. The roof area is entered in square feet and is the total roof space of the building. Building type represents the type of building entered. Users can enter their own entry or choose from a preset option. Preset options include Single-Family Residential Building, Multi-Family Residential Building, Low-Rise Commercial Building, and High-Rise Commercial Building. Climate Zone is the IECC Climate zone that the building is located in. Choices range from IECC Climate Zone 1 to Climate Zone 8. The ceiling height is the height of the ceilings within the building entered in feet. The location is the location of the building. The user can enter their own location or choose from a preset option. Preset options currently include the 50 U.S States.

To save a record, users click the “Save Record” button. If the entered information has a unique building name and index pairing, it will be saved as a new building entry. If it is not a unique building name and index pairing, users will be prompted if they want to save over a previous building entry. Additionally, users can click on a building entry in the database above and click the “Load Building” button to preload the selected building information into the textboxes at the bottom of the interface. The “Copy Building Records” button allows the user to duplicate the building record, including BOM and EUI data, of a selected building to a new building name and index. The “Delete Record” button allows the user to delete a building record, including BOM and EUI data associated with that building.

B2.3 Entering Data into the Bill of Materials Interface

The next step is to add data to the Bill of Materials for the building. This is done by accessing the Bill of Materials Interface through the “Building BOM” button on the Whole Building Dashboard (Figure B3)

FIGURE B3: The Bill of Materials Interface for modifying the bill of materials for building records.

To enter BOM data, users first must choose a building name and index pair to pick a building record they wish to modify BOM data for. The user can also choose to create a building at this step; clicking the Create New Building button will load the Building Info user form to allow the user to create a building before entering BOM data. Next, to enter a material, users interact with the level 1 through level 6 text boxes at the bottom of the interface. Materials are organized within the BOM data through the UNIFORMAT II classification system (Figure B4).

FIGURE B4: The UNIFORMAT II Classification system for Building Elements (Charette & Marshall, 1999).

The level 1 through level 3 data directly matches the UNIFORMAT II Classification system (Charette & Marshall, 1999). Level 4 further refines the individual element, to correspond to a specific part of an individual element.

Users next choose the name of the material being added. All materials are visible by default in the dropdown list in level 5, organized alphabetically. Users can additionally filter the list by data source, choosing to filter for data from GREET1 / GREET 2, user entered data, user modeled data, surrogate data, or any material. Level 6, specifics, is left for the user to add any additional information about the material for their own records. Users enter the material quantity, and the unit into the text boxes on the right. There are a variety of units available in the dropdown list, however the user can also type in their own custom unit. Users then enter the Adjustment factor and Loss/Waste Ratio. The Adjustment factor is a user defined value that directly increases the life cycle emissions of the material. An adjustment factor of 2.0 will multiply the life cycle results by 2.0. The Loss/Waste ratio represents a loss of material during

the construction or use phase of the material, and is entered as a percentage from 0 to 100%. Next, users can either save the material as a new record or click on a record in the preview on the top of the interface and click on “Save over Selected Record” to overwrite a previous record. Finally, users can delete a record by selecting it in the preview and clicking “Delete Record”.

If the unit entered for a material does not match the unit used in the life cycle metrics data, the module will attempt to convert between the units. If unsuccessful, it will prompt the user to enter a unit conversion (Figure B5)

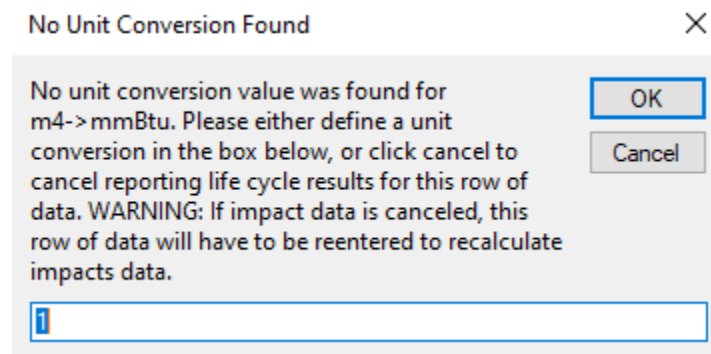

FIGURE B5: The warning that there is no appropriate unit conversion for this material.

B2.4 Entering Energy Use Intensity information through the EUI User Interface

After entering BOM data, the user next enters Energy Use Intensity information. This information handles the operational GHG emissions from a building. To access the interface, users click on the “Building EUI” button on the Whole Building Dashboard (Figure B6).

Energy Use Intensity

Record Lifespan

Enter Records For:

☐ Specific Operational Period

Start Year

End Year

☐ Entire Lifespan of Building

☐ Monthly Reporting
 ☐ Yearly Reporting

Energy Use Intensity

Enter Electricity and Gas Bills

Enter Itemized EUI Information

Enter Total EUI and Energy Source

Save Record

Energy Mix

Pull User-Defined Electricity Provider

Items left to enter:

Step 1: Define a modeling time period and choose either monthly or yearly modeling.

Step 2: Enter the EUI data as bills, an itemized list, or total values per ft2.

Step 3: Enter the electricity provider.

FIGURE B6: The EUI User Interface.

To begin entering EUI data, the user must first choose a building record by clicking on the Load Building button. This will open an interface to choose the building to load. Users then must click on the building they wish to load and click load building (Figure B7). With the building loaded, the user has three steps to complete to calculate EUI impacts. Firstly, the user must choose the timespan of the record, in the “Record Lifespan” box in the bottom right of the interface. The user can enter a specific operational period to model or model the entire lifespan of the building. If the user chooses to model the entire lifespan, the lifespan will be taking from the value entered in the Building Information Interface. Records can be modeled either with monthly reporting, or with yearly reporting.

Building Name	Building Index
Sample Residential Home	1

Exit Without Saving **Load Building**

FIGURE B7: The form to load a building into the EUI interface.

Next, the user must load the Energy Use Intensity information. There are three options for reporting. First, the user can load in values from bills. Clicking the “Enter Gas and Electricity Bills” button opens a form for the user to input the gas bill of the building in therms, and the electricity bill of the building in kWh (Figure B8).

Natural Gas Usage, Therms 0

Electricity Usage, kWh 0

Exit Without Saving **Save and Close**

FIGURE B8: The form to enter Gas and Electricity bill information into the EUI interface.

The user can also choose to enter individual appliance usage information by clicking the “Enter Itemized EUI Information” button (Figure B9). Users enter the name of the appliance, the energy type, the energy use intensity, and the unit into the text boxes on the bottom of the form and click the “Save Item to EUI List” to add an appliance to the list. An item can be deleted from the list by selecting the item in the above list and clicking the “Delete Selected Item in EUI List” button. When the user has entered all appliances, the list is saved with the “Save EUI List and Close” button.

The screenshot shows a window titled "Itemized EUI List" with a close button (X) in the top right corner. Inside the window, there is a table with four columns: Appliance, Energy Type, Energy Use Intensity, and Unit. The table contains four rows of data. Below the table, there are four input fields corresponding to the columns: "Appliance/Equipment" (text box), "Energy Type" (dropdown menu), "Energy Use Intensity" (text box), and "Unit" (dropdown menu). Below these input fields are four buttons: "Save Item to EUI List", "Delete Selected Item in EUI List", "Exit Without Saving", and "Save EUI List and Close".

Appliance	Energy Type	Energy Use Intensity	Unit
Appliance 1	Electricity	100	kWh
Appliance 2	Electricity	151	kWh
Appliance 3	Gas	156	kBTU
Appliance 4	Gas	1.560	Therms

Below the table, the input fields are populated with the data from the last row of the table:

- Appliance/Equipment: Appliance 4
- Energy Type: Gas
- Energy Use Intensity: 1.560
- Unit: Therms

The buttons at the bottom are:

- Save Item to EUI List
- Delete Selected Item in EUI List
- Exit Without Saving
- Save EUI List and Close

FIGURE B9: The interface to add an itemized EUI list to the EUI interface.

Finally, the user inputs the energy provider by clicking the “Pull User-Defined Electricity Provider” button to load the provider interface (Figure B10). In this interface, the user chooses the location, either the National US or an individual U.S. state, and then chooses the electricity provider in the text boxes. In the current version, only the national average and state averages are available by default in the system.

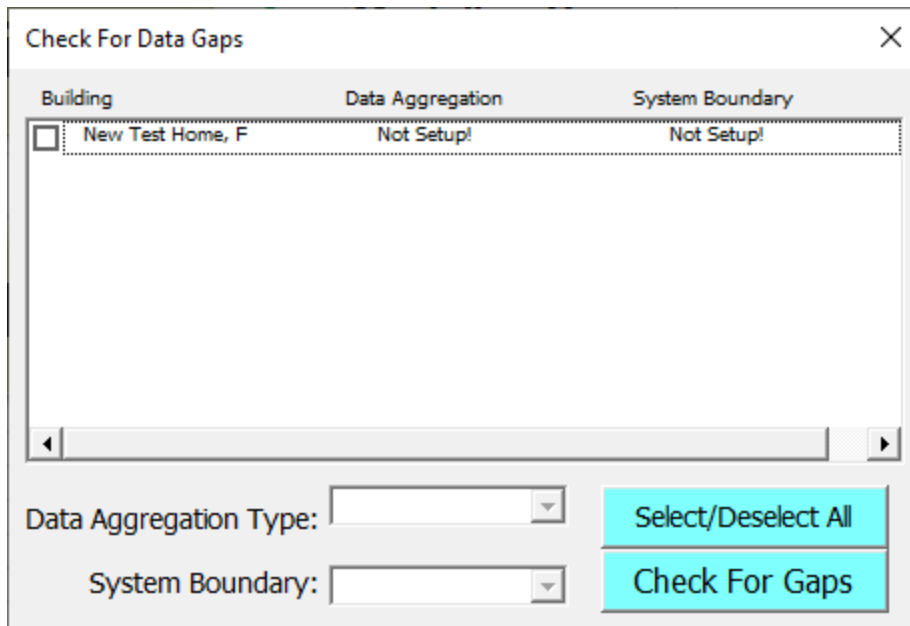

The image shows a software dialog box titled "Energy Provider". It contains two dropdown menus: "Location (State within US)" and "Electricity Provider". Below these is a button labeled "Save and Close".

FIGURE B10: The Energy Provider Interface.

When the user has entered the modeling lifespan, the energy use intensity, and the energy provider, the EUI is ready to be saved. Clicking the “Save Record” button will save the EUI record to the database and calculate the operational GHG usage. Depending on the size of a record and the speed of the computer, saving can potentially take up to a couple minutes. In this time, excel will lock up, and appear frozen. The time can be shorted by closing other applications on the computer before saving. While EUI data is saving, please do not close excel.

B3 DATA GAPS AND UNIT CONVERSION ISSUES DURING WHOLE BUILDING LCA

Data gaps in the Whole Building Analysis section are resolved very similar to the methods in Building Component Analysis. The user begins by clicking the “Address Data Gaps” button located on the Whole Building LCA worksheet. This opens a user form for the user to specify the system boundary and data aggregation of each building, as well as select which buildings to check for data gaps and issues in unit conversion, shown in Figure B11.

The dialog box titled "Check For Data Gaps" contains a table with three columns: "Building", "Data Aggregation", and "System Boundary". The first row shows a checkbox, "New Test Home, F", "Not Setup!", and "Not Setup!". Below the table are two dropdown menus for "Data Aggregation Type" and "System Boundary", and two buttons: "Select/Deselect All" and "Check For Gaps".

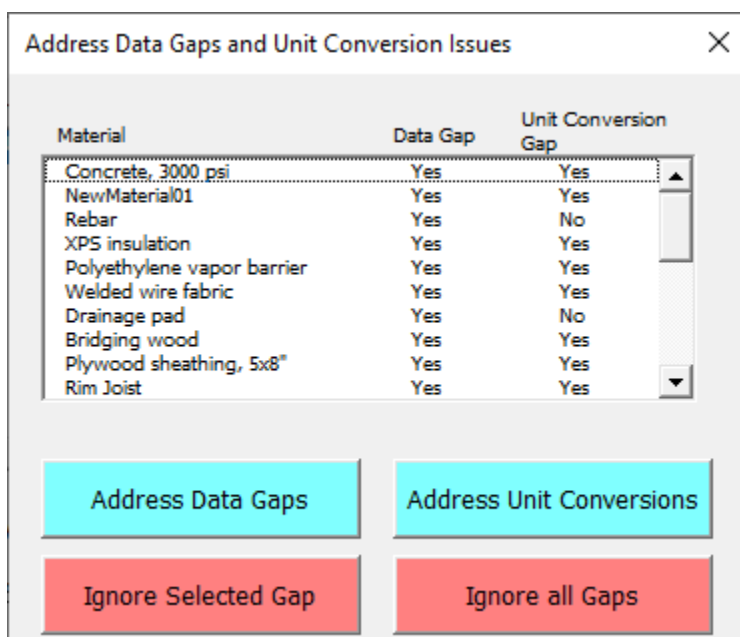

Building	Data Aggregation	System Boundary
<input type="checkbox"/> New Test Home, F	Not Setup!	Not Setup!

Data Aggregation Type: Select/Deselect All

System Boundary: Check For Gaps

FIGURE B11: The form for selecting buildings to check for data gaps.

The user can select one or more buildings in the list of buildings on this user form. Then, the user sets the data aggregation type, either aggregated to the system boundary or disaggregated to the life cycle stage, and system boundary, and selects Check for Gaps. The selected buildings are then checked for data gaps; if any data gaps or unit conversion issues are found, a user form will appear to guide the user through the process of correcting these issues. The first user form, shown in Figure B12, displays the list of materials used in the selected buildings that are either data gaps, have unit conversion issues, or both.

The dialog box titled "Address Data Gaps and Unit Conversion Issues" contains a table with three columns: "Material", "Data Gap", and "Unit Conversion Gap". The table lists materials and their corresponding gap status. Below the table are four buttons: "Address Data Gaps", "Address Unit Conversions", "Ignore Selected Gap", and "Ignore all Gaps".

Material	Data Gap	Unit Conversion Gap
Concrete, 3000 psi	Yes	Yes
NewMaterial01	Yes	Yes
Rebar	Yes	No
XPS insulation	Yes	Yes
Polyethylene vapor barrier	Yes	Yes
Welded wire fabric	Yes	Yes
Drainage pad	Yes	No
Bridging wood	Yes	Yes
Plywood sheathing, 5x8"	Yes	Yes
Rim Joist	Yes	Yes

Address Data Gaps Address Unit Conversions

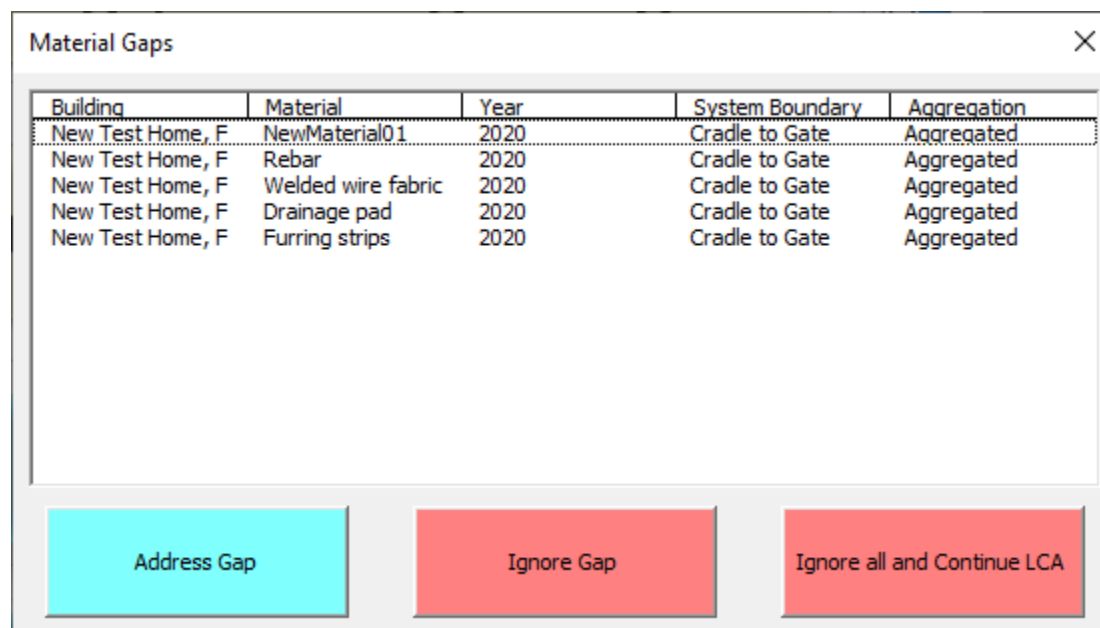

Ignore Selected Gap Ignore all Gaps

FIGURE B12: The window showing materials that are data gaps and/or need unit conversions applied to them.

B3.1 Resolving Data Gaps during Whole Building LCA

Clicking the address data gaps button will load the user forms for resolving data gaps. A user form will appear, showing a list of the data gaps, including the material, building, year, system boundary, and data aggregation level, shown in Figure B13. To address a data gap, the user needs to click on a data gap in the list, then click address gap. Additionally, the user can choose to ignore a data gap, or ignore all data gaps and continue the LCA. Note that ignoring a data gap will result in inaccurate data, as any data gaps will have no life cycle data associated with them.

Data gaps in Whole Building LCA process can be resolved in a similar fashion to data gaps in the Building Component LCA process. A data gap can be resolved by modeling the material in BC Analysis, inputting LC Metrics manually, or using a surrogate. Modeling a material in BC Analysis and inputting LC Metrics manually perform identically to the processes in modeling Building Component Analysis data gaps. The surrogate method is similar but offers additional information for Whole Building modeling. A list of surrogates is listed from the aggregated LCProfiles worksheet, including the year of data available, the system boundary of the material, and the data aggregation level. This allows the user to choose a surrogate while being aware of the surrogate's data aggregation level and system boundary. The user then chooses to load the surrogate, which will resolve the gap. When all gaps are resolved, the LCA can continue.

Building	Material	Year	System Boundary	Aggregation
New Test Home, F	NewMaterial01	2020	Cradle to Gate	Aggregated
New Test Home, F	Rebar	2020	Cradle to Gate	Aggregated
New Test Home, F	Welded wire fabric	2020	Cradle to Gate	Aggregated

Load Surrogate Data Cancel Without Loading

FIGURE B15: The user form for loading a surrogate to address a whole building modeling data gap.

B3.2 Resolving Unit Conversion Issues During Whole Building LCA

To address any unit conversion issues, click the appropriate button in the check gaps user form, shown in Figure B12. This will open a user form to aid the user in addressing unit conversion issues. The list box shows what materials have conversion issues, as well as what unit is specified in the bill of materials, the unit in the database, and the unit conversion found, as well as a notice to the user whether the gap has been resolved.

To resolve a gap, the user clicks on a material in the list, and types of the desired unit conversion into the text box. Note that if a material is listed as having No Unit Found in Database, that material is also a data gap; data gaps must be resolved before unit conversions can be addressed. The user then selects whether the unit conversion should be usable for all materials, or only the selected material. Finally, the user clicks Resolve Gap to save the unit conversion. Alternatively, the user can select Resolve all Gaps and Continue to set all unit conversions to a value of 1.0. Note that this is intended in a similar fashion to the ability to ignore data gaps and may result in inaccurate results if the unit conversions are not considered during analysis of the life cycle data.

Material	Unit in BOM	Unit in Database	Unit	Gap Resolved?
Concrete, 3000 ps	ft3	No Unit Found in	-1	No
NewMaterial01	lb	No Unit Found in	-1	No

☐ Yes ☐ No

FIGURE B16: The User form for addressing data gaps.

B4 RUN EMBODIED AND OPERATIONAL LIFE CYCLE ANALYSIS

To calculate the embodied and operational life cycle results, click on the “Run Whole Building Embodied & Operational Calculations” button. This will calculate the embodied metrics for all BOM data, and the operational metrics for all EUI data. Depending on the amount of data, this could take several minutes. During this time, excel will appear frozen. To speed up the process, please close any background applications before running calculations. Please do not close excel during calculations, as this may result in unsaved data.

B5 WHOLE BUILDING SENSITIVITY ANALYSIS

In addition to Standard LCA, the Whole Building Analysis Module is equipped to configure sensitivity analysis, allowing for the analysis of a variety of changes to a singular base case. The sensitivity analysis functions can be accessed by selecting a building to run, as with standard LCA, by clicking the Configure Sensitivity Analysis button, shown in Figure B17. This will open the user interface for configuring sensitivity analysis. Note that multiple buildings can be selected for analysis at the same time; if multiple buildings are selected in the list prior to clicking on the Sensitivity Analysis button, then the bills of materials for all selected buildings will be available for configuration. This allows the user to configure multiple buildings for sensitivity analysis at the same time. Note that each sensitivity analysis case will be kept separate, and configuring multiple buildings at the same time will still result in separate sensitivity analysis per building being carried out.

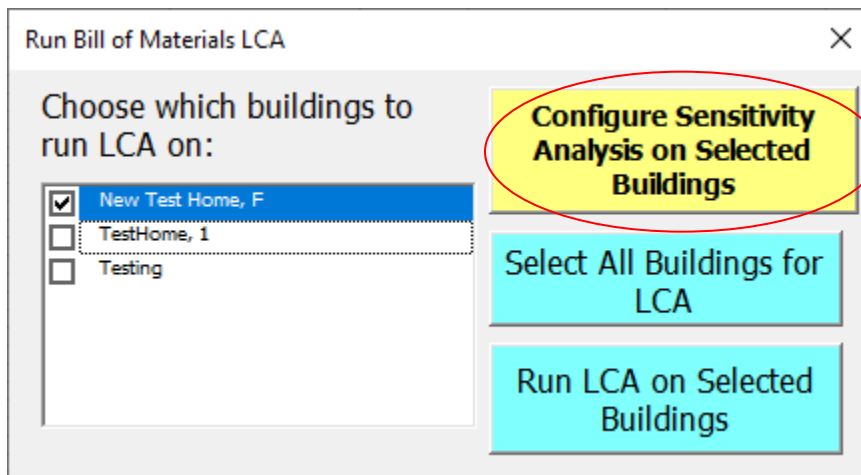

FIGURE B17: The button to access sensitivity analysis.

Master Index	UNIFORMAT Lvl 4	Material Comments Lvl6	Default Material

FIGURE B18 The user interface to configure sensitivity analysis.

To configure a sensitivity analysis case, the user clicks on the desired material in the list at the top of the user form. Then, in the five sections below, the user can configure changes to the material, quantity, replacement frequency, loss factor, or adjustment factor. For each sensitivity type, a scenario name option is added to aid the user in creating meaningful names or descriptions for each sensitivity case. These scenario names will be used to set up the dynamic visuals in the Sensitivity Analysis Dashboard. For configuring the material type, the user can choose a material from the dropdown list at the top right of the section, choose the material quantity and unit, and then click Add Material Option to add the option. This will add the desired case to the list. A case can be deleted by clicking on it in the list, then clicking delete highlighted values.

To configure the quantity, replacement frequency, loss factor, and adjustment factor, a desired value can be added into the text box, then the Add button clicked. This will add the individual value as a sensitivity case. In addition, the user can choose to add changes in steps, either by absolute value or as a relative percentage of the base case. To do so, the user specifies a total change as a value +/- the base case, and the step value, as well as whether the change is

absolute or as a relative percentage. For example, for a base case of 50, having a change of 10 with a step of 5 will result in the values {40, 45, 50, 55, 60} being added if the change is in absolute value, or {45,47.5,50,52.5,55} if the change is a relative percentage. Similar to the material option changes, the user can specify a scenario name, unique to each sensitivity analysis type, to aid in describing the cases, as well as delete values by clicking on them in the list of added values and clicking delete values.

Finally, the user can entirely copy a sensitivity analysis setup from one material to another. Starting from the material being copied, the user clicks the copy material setup button, then clicks on the desired material to be pasted on in the list at the top of the user form, before clicking paste material setup. This will copy all of the sensitivity analysis setup to the desired material(s). When the user has set up the desired sensitivity cases, clicking the Run Sensitivity Analysis button will run the analysis. If the user changes the material type or replacement period, then the data gaps feature will have to be re-run, as a data gap would affect the results from these changes. If this occurs, the data gap feature will occur, and the process will be the same as described in section B3. Please note that, depending on the number of cases added, this process could take multiple minutes, and Excel could be frozen during this time. Afterwards, a message box will appear notifying the user that the analysis is complete. Results can then be viewed in the sensitivity analysis Dashboard.

B5.1 Viewing Sensitivity Analysis Results

Results from the sensitivity analysis can be viewed in the Sensitivity Analysis Dashboard worksheet. This worksheet contains a tornado chart to view the changes in GHG emissions, viewed as a percentage change from the base case, as well as a table showing the absolute change in each LC Metric for each sensitivity case.

SUMMARY OF CHANGES IN EACH LIFE CYCLE METRIC FOR EACH SENSITIVITY CASE

Row Labels	Sum of Total Energy Change	Sum of Fossil Fuels Change	Sum of Coal Change	Sum of Natural Gas Change	Sum of Water Consumption Change	Sum of Petroleum Change	Sum c

FigureB19: The tornado chart for the change in GHG emissions.

B6 MANUALLY ENTER DATA OUTSIDE OF USER INTERFACES

The GREET Building Module supports the user manually entering data into the data worksheets. To begin, click the “Manual Data Entry” button on the Whole Building Dashboard. This will open an interface to access the background worksheets for Building Information, BOM Information, and EUI Information (Figure B20). Clicking one of the three buttons will open the respective worksheet for entering data. It is highly recommended that the user enters Building Information first, following by Bill of Materials Information, and then Energy Use Intensity Information.

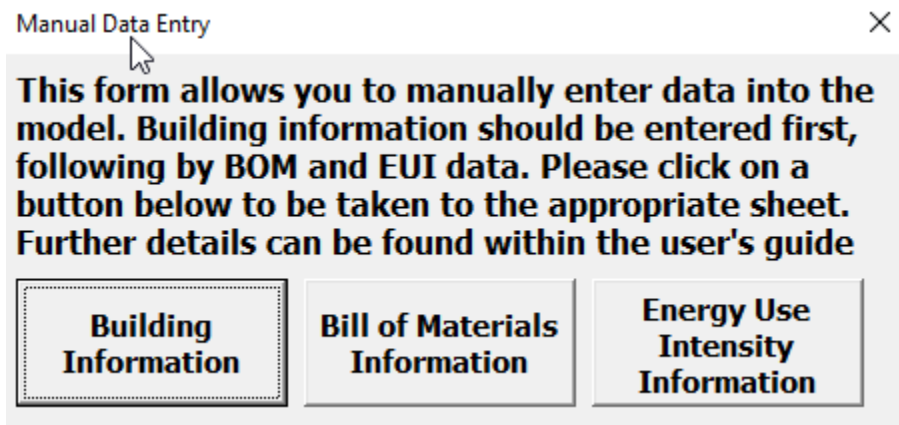

FIGURE B20: The User Interface to access background data worksheets for manual data entry

B7.1 Manually Enter Building Information

Building Name	Building Index	Building Type	Location	Climate Zone
Sample Residential Home	1	Single-Family Res	Illinois	IECC Climate Zone

FIGURE B21: A portion of the Building Info Worksheet

Clicking the “Building Information” in the manual data entry interface (Figure B19) will open the “Building Info” Worksheet (Figure B20). Each row corresponds to a building entry. Values can be manually entered into the form, following the format described below:

Columns A-B: The building name and index. Each row must have a unique name and index pair.

Column C: The Type of Building. Default values include Single-Family Residential Building, Multi-Family Residential Building, Low-Rise Commercial Building, and High-Rise Commercial Building; however, any value can be entered. This value is optional.

Column D: The location of the building. Default values include the U.S. states, although any value can be entered. This value is optional.

Column E: The climate zone of the building. It is highly recommended to follow the IECC Climate Zones. This value is optional.

Column F: The total floor area of the building. Values must be a positive number. This value is required.

Column G: The total roof area of the building. Values must be a positive number. This value is optional.

Column H: The number of floors present in the building. Values must be a positive whole number. This value is optional.

Column I: The height of the ceilings within the building. Values must be numerical. This value is optional.

Column J: The amount of years the building will remain in operation. Values must be a positive whole number. This value is required.

Column K: The amount of years a retrofitted building has already been in operation. Values must be a positive whole number. This value is optional.

Column L: The master index is used by the module to index for buildings. The format is “(Building Name from Column A), (Building Index from Column B)”. This value is required, and the format must be strictly followed.

B7.2 Enter Bill of Materials Data Manually

R	S	T	U
Level 5, Building Materials	Level 6, Material Specification	Material Quantity	Material Unit
Gypsum wall board		100.0	m2
Concrete slab		151.0	m3
Flat Glass		10.0	kg
Copper		105	kg
Steel		3	kg
Steel		351	kg
Sand		500	ton

FIGURE B21: A portion of the Bill of Materials Data Table.

Clicking the “Bill of Materials Information” in the manual data entry interface (Figure B20) will open the “WB BOM & Results” Worksheet (Figure B22). Each row corresponds to a material entry. Values can be manually entered into the form, following the format described below:

Columns A-L: These values correspond to the building that the material is part of. Values match the values in the “Building Info” worksheet. Values should be identical between the desired building record in the “Building Info” worksheet and the desired material row. Please note that the master index is found in column C on the “WB BOM & Results” worksheet instead of column N. These values are required.

Columns M-P: These values represent the four UNIFORMAT II values used in material classification. Please refer to the “UNIFORMAT II” worksheet for accepted values, accessible by clicking the “UNIFORMAT II” button on the Whole Building Dashboard. These values are required, and the format must be followed.

Column Q: The name of the material. Any name can be entered. If a material is entered that is not present in the life cycle metrics data, it will be a data gap. Please check the data gaps feature (See Section B1.2) before calculating results. This value is required.

Column R: This column holds specific notes about a material. Any value is accepted. This value is optional.

Column S: The quantity of material. Values must be a positive number. This value is required.

Column T: The unit of the material being added. Any value is accepted. If the unit is not the same as the unit used in the life cycle metrics being calculated, the user will be prompted to add a unit conversion.

Column U: The replacement period of the material. Any positive value is accepted; the material for this row will be replaced every X years, where X is the value entered.

Column V: The % of material lost in calculation. Values are entered as a percentage, from 0 (inclusive) to 100 (exclusive). This value is required. No material loss is represented by 0.

Column W: The system boundary. Accepted values are Cradle to Gate, Cradle to Construction, Cradle to Use, Cradle to Grave, and Cradle to Cradle.

Column X: The data aggregation type. Accepted values are Aggregated for data aggregated to the system boundary, and Disaggregated for data aggregated to the life cycle stage. All values for a given building must match!

Column Y: The adjusting factor for the life cycle metrics. Provides a multiplier to the life cycle metrics data. Any positive numerical value is accepted. This value is required and unless needed should be set to 1.

Columns Z-AZ: These columns are used by the module to hold life cycle metrics. These will be filled in when the user calculates embodied carbon results (See Section B1.3) or when the user enters a material through the BOM Interface (See Section B1.1.2). Users should not manually enter data into these columns. Any data entered will be overwritten when calculations are run.

B7.3 Enter EUI Information Manually

MasterIndex ▾	Lifespan ▾	Operational Year ▾	Operational Month ▾	EUI ▾	Energy Type ▾	Unit ▾
Sample Reside	60	1			1 Electricity	kWh/ft2
Sample Reside	60	1			2 Gas	kBTU/ft2
Sample Reside	60	2			1 Electricity	kWh/ft2
Sample Reside	60	2			2 Gas	kBTU/ft2
Sample Reside	60	3			1 Electricity	kWh/ft2
Sample Reside	60	3			2 Gas	kBTU/ft2
Sample Reside	60	4			1 Electricity	kWh/ft2
Sample Reside	60	4			2 Gas	kBTU/ft2

FIGURE B22: A portion of the EUI Info data table.

Clicking the “Energy Use Intensity Information” button in the manual data entry interface (Figure B19) will open the “EUI Info & Modeling Results” (Figure B22). Each row corresponds to a year or month entry. Values can be manually entered into the form, following the format described below:

Column A: Holds whether the column holds Gas or Electricity data. Must be either Gas or Electricity.

Column B: The energy source. Value must match the desired electricity generation mix, or “Natural gas for space heating, per mmBtu input”

Column C: The master index of the building record being used. The format is “(Building Name), (Building Index)”. This must match a building record present in the “Building Info” worksheet and is required.

Column D: This is the lifespan of the building record being used. This must match the lifespan of the building record chosen in column A. This value is required.

Column E: This is the year represented by the EUI record being inputted. Accepted values are positive whole integers from one to the lifespan of the building. This value is required.

Column F: This column allows for monthly reporting. This value is optional. Values include 1 – 12, to correspond with January – December respectively. If unused, the model will be yearly values, and should be left blank.

Column G: The Energy Use Intensity being reported. Accepted values are positive numbers. This value is required.

Column H: The Unit of the EUI being reported. Accepted values are dependent on the reporting type; please see column J. This value is required.

Column I: This is the EUI value from column G, converted to mmBTU/reporting period. This value is required.

Column J: This column is the name of the appliance or equipment being modeled, if the modeling is done on an appliance basis as defined by Column J. If the user is not modeling on an itemized level, this column should be left blank.

Column K: This column is the electricity provider. Acceptable values are “(State) State Average”, where (State) is the name of a U.S. State, or “U.S. National Average”. This value is required.

Column L: This column represents the reporting method for the EUI data. Accepted values are “Bills”, “Totals”, or “Items”. If the reporting method chosen is “Bills”, there must be two rows per year/month, depending on the reporting period; one row with the electricity energy type, reported in kWh, and one row with the gas energy type reported in therms. If the reporting method chosen is “Totals”, there must be two rows per year/month, depending on the reporting period; one row with the electricity energy type, reported in kWh/ft², and one row with the gas energy type reported in kBtu/ft². If the reporting method chosen is “Items” then there must be one row per appliance per year/month. The appliance name must be entered into column H. Accepted units in column G are kWh for electricity, and kBtu or therms for gas.

B7 VIEWING AND INTERPRETING LIFE CYCLE RESULTS

The results of the embodied and operational life cycle calculations can be viewed on the Whole Building Results Dashboard, found on the “Dashboard_WB” Worksheet. This worksheet can be accessed with a button on the “Whole Building Modeling” Worksheet. Results are broken into three categories. First, the embodied GHG emissions. Second, the operational GHG emissions. Thirdly, the summary of the Bill of Materials.

B6.1 View and Explore Embodied GHG Results

The embodied GHG results are displayed as a series of PivotCharts on the Whole Building Results Dashboard (Figure B23). **It is necessary to click the “Refresh Data” button after running Whole Building LCA to refresh the results.** There are four PivotCharts displayed. The farthest left pivot chart shows the total embodied GHG emissions of each building record. The middle-left pivot chart shows a pie chart displaying the portion of GHG emissions reported by each Level 2 group element. The middle pivot chart shows the GHG emissions by each level 2 group element. The middle right pivot chart displays the GHG emissions by each level 3 individual element. The furthest right pivot chart shows the GHG emissions for each material. Additionally, users can choose to select only specific materials through a variety of buttons to control the pivot table (Figure B24). Selecting a button will enable only that option to be shown on the pivot table. Holding left shift and clicking multiple buttons will display all clicked options in the results.

FIGURE B23: The first two PivotCharts displaying Embodied GHG Emissions results.

FIGURE B24: The buttons for selecting/deselecting results to be displayed in the PivotCharts for embodied GHG emissions.

B6.2 View and Explore Operational GHG Emissions

The operational GHG results are displayed as a series of PivotCharts on the Whole Building Results Dashboard (Figure B25).). **It is necessary to click the “Refresh Data” button after running Whole Building LCA to refresh the results.** The pivot chart displays the operational GHG emissions by year for the selected building. To display results for a desired building, click the building name desired in the right most list in the Operational GHG options (Figure B26). To display multiple buildings at once, hold the left shift key and click on the desired building names. Additionally, the user can select to only view one time of energy type (Gas or Electric), filter by energy source, operational year, or appliance/equipment.

FIGURE B25: The PivotCharts displaying the operational GHG emissions from a selected building record.

2) Whole Building Operational GHG Emissions

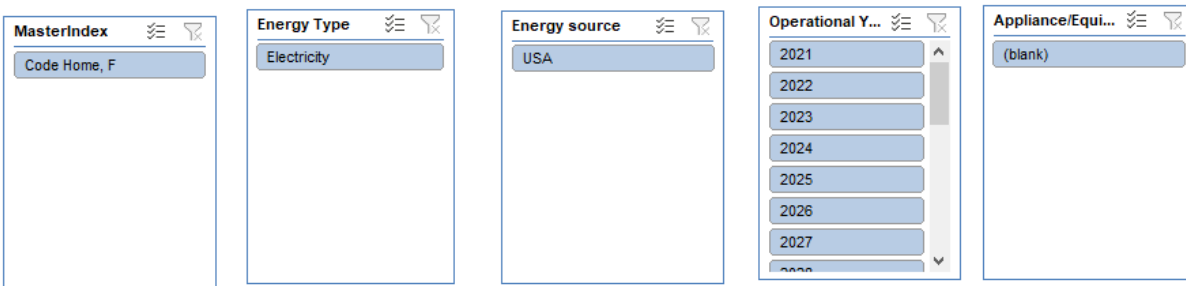

FIGURE B26: The controls for the operational GHG emissions pivot tables.

B6.3 View the Bill of Materials

Below the Embodied and Operational GHG emissions displays is the summary of Building Bill of Materials. This allows the user to see the total quantity of materials in the bill of materials for a selected building (Figure B27). The table can be filtered for a desired building time, or to display the bill of materials for a single building (Figure B28).

Sum of Material Quantity	Column Labels			A SUBSTRUCTURE Total
	<input type="checkbox"/> A SUBSTRUCTURE <input type="checkbox"/> A10 Foundations <input type="checkbox"/> A1010 Standard Foundations <input checked="" type="checkbox"/> A101001 Wall Foundations			
Row Labels		A10 Foundations Total		
Concrete slab				
Gypsum wall board	100.0	100.0	100.0	100.0
Flat Glass				
Grand Total	100.0	100.0	100.0	100.0

C BACKGROUND DATA WORKSHEETS

The GREET Building Module is designed to enhance transparency and consistency, which are key to reliability and comparability of the modeling results. To achieve this goal, we make the background database accessible to the user for view, modification, update, and expansion, which is an important feature to remedy some of the gaps in the LCA models we reviewed (Cai et al., 2021).

Several background datasheets are available to be viewed and are accessible through the “Building Module” worksheet, via buttons on the bottom of the sheet (Figure C1). Note that these buttons are dual functional, which open and hide the worksheet with one click and another. See below an introduction to what is included in each background worksheet.

To access to background databases and details of modeling results, please click the following buttons:

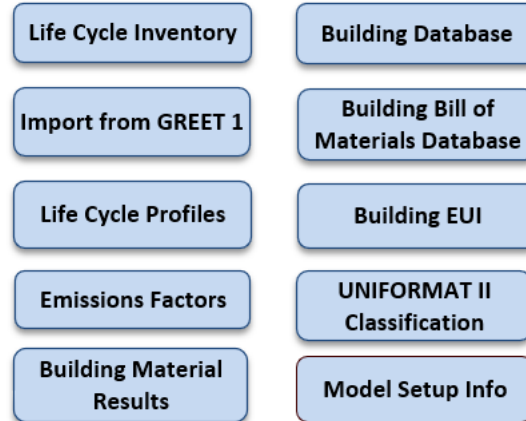

FIGURE C1: The background databases and detailed model results.

C1 LIFE CYCLE INVENTORY

This worksheet contains the life cycle inventory, such as material and energy requirements, along the supply chain of building materials based on the user inputs from the GUI available in the BC Analysis worksheet. This worksheet serves as an LCI repository of all building materials that are currently being modeled with the Module.

C2 LIFE CYCLE PROFILES

This worksheet contains the life cycle profiles for each material that are that imported from the GREET Fuel Cycle model (known as GREET 1), GREET Vehicle Cycle model (known as GREET 2), open literature such as EPDs, or generated through simulation with the Module. For a given material, its life cycle profile includes 27 life cycle metrics and associated information such as unit, functional unit, representative year, comment, and source of the data.

Life cycle profiles are stored for each material for every year from 2020 to 2080. Table C1 shows the life cycle profile of coal as an example., This worksheet forms the background database of common materials, process fuels, chemicals, etc., as well as newly added and/or generated data that may be involved in modeling new building materials. This worksheet is only used for building material LCA, and as such, the life cycle profiles in this database all have a Cradle to Gate system boundary.

TABLE C1. Life cycle profile of coal as an example. Data continues for every year until 2020.

C3 DISAGGREGATED LIFE CYCLE PROFILES

This worksheet contains the life cycle profiles for each material that are that imported from the GREET 1, GREET 2, open literature such as EPDs, or generated through simulation with the Module. For a given material, its life cycle profile includes 27 life cycle metrics and associated information such as unit, functional unit, representative year, comment, and source of the data. Life cycle data is stored at the life cycle stage level, as well as aggregated to the system boundary. Life cycle profiles are stored for each material on an individual year basis. Table C2 shows the life cycle profile of Aniline as an example.

This worksheet forms the background database of common materials, process fuels, chemicals, etc., as well as newly added and/or generated data that may be involved in modeling new buildings. This worksheet is only used for whole building LCA.

TABLE C2. Disaggregated Life cycle profile of Aniline as an example.

C4 EMISSIONS FACTORS

This worksheet contains emission factors of GHGs, which include carbon dioxide (CO₂), methane (CH₄), and nitrous oxides (N₂O) and criteria air pollutants, which include nitrogen oxides (NO_x), carbon monoxide (CO), particulate matter with a diameter of less than 2.5 and 10 micrometers, respectively (PM_{2.5} and PM₁₀), sulfur oxides (SO_x), and volatile organic compounds (VOCs), that are related to combustion of process fuels, such as natural gas, coal, residual oil, etc., with specific combustion technologies, such as a boiler, a kiln, etc. These emission factors come from GREET 1.

C5 BUILDING COMPONENTS RESULTS

This worksheet contains detailed life cycle results of building materials that are modeled. The embodied energy consumption, GHG emissions, water consumption, and criteria air pollutant emissions associated with each input of process energy or material along the life cycle stages of the defined system boundary applied in the modeling are itemized. This is the results dataset used to visualize the details in the dynamic Dashboard for building materials, building components, and building technologies.

C6 IMPORTS FROM GREET 1

This worksheet contains imports of emission factors related to transportation and electricity generation at the national and state level from GREET 1. These values are taken directly from GREET 1. It is recommended to work with GREET 1 instead of modifying the values on this worksheet.

C7 UNIFORMAT II CLASSIFICATION

This worksheet holds the UNIFORMAT II Classification for building elements and construction work used in the Bill of Materials database. The structure conforms to the ASTM E1557 Standard.

C8 BUILDING DATABASE

Please see section B5.1 for information on the building database.

C9 BILL OF MATERIALS DATABASE

Please see section B5.2 for information on the bill of materials database.

C10 EUI DATABASE

Please see section B5.3 for information on the EUI database.

C11 MODELSETUPINFO

This worksheet contains general model setup information that is used primarily by dropdown lists, such as the list of default functional units available, in the graphical user interface for building material modeling. The user can access to this worksheet to expand the default options available for the dropdown lists to serve unique modeling needs.
